RADIOLOGY—Chairman Edward L Jenkinson Chicago Vice Chairman Ross Golden New York Secretary John T Murphy 421 Michigan Street Toledo Ohio

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER 1935

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals except those starred will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation, "E," Editorial, "C," Correspondence, "ML," Medical Economics, "ab" abstract, the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should therefore look for the subject word with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under American Medical Association. The name of the author in brackets follows the subject entry.

For author index see page 2246.

emotional excitement effect on of normal
human beings 123—E
environmental temperature effect on [Gott-
lieb] 1637—ab
estrogenic principle effect on [Mazer &
others] *250
exercise tolerance tests in regard to 303
high 1703
high and endocrinology [Barr] *1766
high and renal denervation [Uebelhör] 1564
—ab
high arterial electrocardiographic changes in
[Ryckert] 2185—ab
high arterial tension and cardiac reserve 2177
high arterial tension cases left best un-
treated 1310—ab
high basophilic cell infiltration in neuro-
hypophysis in [Ahlström] 1814—ab
high blood of patients [Carriéro] 1561—ab
high committal depressor principles [Bis-
kind] *675
high essential with encephalopathy 1060
high experimental 286—E
high heart in [Fahr] *1396
high hypertensive heart disease [Sprague &
White] *1392
high in Chicago area [Maber & others] *263
high in cutaneous vessels in preclampsia
[von Raiz] 752—ab
high kidney changes in [MacMahon] 2112
—ab
high stimulating thyrotoxicosis [Hamilton]
545—ab
high surgical treatment 816
high too much reliance on laboratory results
523
high use of whey in 1542
high with experimental oxalate nephritis
[Arnott] 637—ab
increase in indicates secretory disorders in
myoma [Strassmann] 2025—ab
dinitrophenol effect on [Tainter & others]
*334
normal physiologic standards 1210
recording Forman fined for on boardwalk
Atlantic City 2079
self determinations 1526—E
BLOOD TRANSFUSION agglutination tests be-
fore 737
donor (univocal) [Hesse] 1644—ab
donors organization in Germany 016
for jaundiced patients [Judd & others] *1653
hemolytic reaction with oliguria [McCand-
less] *852
history Francesco Folli first employed 1928
immunotransfusions in hemolytic streptococcus
infections [Lyons] *1972
in childhood [Schäffer] 1816—ab
in chronic skin disorders [Kuske] 624—ab
in obstetric hemorrhage [Diedmann] 626
—ab
Italian decree regarding 734
long distance transportation of blood for 296
of plasma in hemolytic shock [Helmutz] 924
—ab
of preserved blood [Karavancov] 240—ab
2001
repeated necessary to recross match a patient
and donor 737
sodium citrate in 740
therapeutic action, injecting epinephrine im-
proves [Boller] 164—ab
BLOOD VESSELS See also Arteries Capil-
laries Vasomotor Mechanism Veins

THE SPECIFICNESS OF CERTAIN HEMOLYTIC STREPTOCOCCI

HONORARY CHAIRMAN'S ADDRESS

LUDVIG HEKTOEN, MD
CHICAGO

In the years since the organization of this section, great advances have been made in the study of the pathogenic streptococci. It is not my intention to review these advances in detail. The problem whether there are specific pathogenic streptococci has not been settled, and I wish to discuss briefly and in a general way only the question whether the streptococci that cause erysipelas and scarlet fever are distinct groups or species of streptococci.

There can be no question about the etiologic relationship of hemolytic streptococci to erysipelas and to scarlet fever, but there is lack of agreement on the relationship of these streptococci to each other and to hemolytic streptococci in general. There are two principal and opposing views concerning this relationship. One that all streptococci in question form one group in which are no members with fixed and distinctive pathogenic properties. According to this view there is really only one pathogenic hemolytic streptococcus that may cause different processes of disease in man, depending on variations in virulence, in toxigenesis, in resistance and in other conditions. The second view holds that there are distinct pathogenic groups among the hemolytic streptococci. At present the strongest claims for recognition as distinct pathogenic groups are made for the streptococci of erysipelas and of scarlet fever, but similar claims are made also for the streptococci of septic or epidemic sore throat and of puerperal fever, at least in some of the instances.

To go back briefly, new doubts about the unity of hemolytic streptococci arose when it was found that according to specific agglutination and opsonification the streptococci of scarlet fever and of erysipelas form what seemed to be distinct and closed groups. Then came the Dick discoveries that scarlet fever is caused by hemolytic streptococci, that scarlet fever like diphtheria is a toxin disease, and that the streptococci of scarlet fever and of erysipelas (Birkhaug) appeared to produce distinct toxins with specific antigenic and other properties. Here it may be emphasized that the toxin of scarlet fever streptococci is something more than just erythrogenic. It has wider action. In susceptible persons it causes vomiting and other symptoms of scarlet fever in addition to the redness of the skin.

But strenuous objections have been made to the conclusion that these streptococci are endowed with such immunologic and toxigenic specificness that they constitute distinct groups or species. Many results, sometimes bewildering, have been published as showing that pathogenic hemolytic streptococci produce the same toxins. It has been pointed out that in working with hemolytic streptococci, their toxins and their antigenic properties there is greater danger than seems to have been realized at all times of faulty methods. Tests with cultures of doubtful origin and purity and with unreliable and unstandardized toxins and serums without any value. And the influence of dissociation on the specificness of the reactions of hemolytic streptococci has not received any consideration until just recently. It is quite probable that some investigations of streptococcus specificness have yielded results of uncertain value because unstable and dissociating strains were used. It appears certain that dissociation may modify the antigenic as well as other properties of the stable state of an organism.

The view that the streptococci of scarlet fever and of erysipelas are specific agents receives support from experiments with their toxins, from observations on their immunologic and cultural characteristics and from the relations of the two diseases to each other.

The skin tests with the toxins of erysipelas and of scarlet fever are significant. Birkhaug¹ found that the erythrogenic action of the erysipelas toxin was neutralized by immune erysipelas serum but not by scarlet fever antitoxin. I shall cite the results of G. F. Dick and G. H. Dick² more in detail because they have not received the consideration their significance demands. Carefully standardized materials were used. Of 500 persons of all ages, 36 per cent reacted to the scarlet toxin and 46.4 per cent to the erysipelas toxin. Of those insusceptible to the scarlet toxin, 42.1 per cent were susceptible to the erysipelas toxin. Of those insusceptible to the erysipelas toxin, 31.3 per cent were susceptible to the scarlet toxin. Of 100 convalescents from scarlet fever, the Dick test having turned negative, 52 per cent reacted to the erysipelas toxin. Twenty-four susceptibles to both toxins were immunized with the scarlet toxin and when the skin no longer reacted to that toxin the reaction to the erysipelas toxin remained positive. Finally, tests with antitoxic horse serums gave strictly specific neutralization. These results establish that the streptococci of scarlet fever and of erysipelas are distinct at least in the sense that they produce specific toxins. Differences in the antigenic powers of these toxins may explain why the immunity after scarlet fever is permanent while in erysipelas the immunity is more transitory.

From the John McCormick Institute for Infectious Diseases.
Read in the anniversary program by founders of the section before the Section on Pathology and Physiology at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1935.

1 Birkhaug, K. E. Studies on the Biology of Streptococcus Erysipelatis. IV. Toxin Production of Streptococcus Erysipelatis. Proc. Soc. Exper. Biol. & Med. 23: 201, 1925-1926.

2 Dick, G. F., and Dick, Gladys H. Specificity of Soluble Toxins Produced by Hemolytic Streptococci. J. A. M. A. 93: 1784 (Dec. 7) 1929.

The recent work by Ruth Tunnichliff³ with stable as well as unstable strains of streptococci confirms the earlier results,⁴ showing that the streptococci of scarlet fever and of erysipelas form distinct groups according to their agglutination and opsonification as well as according to their absorption of agglutinins and opsonins. It is interesting to note that streptococci from epidemic sore throat may not fall into either of these two groups. Tunnichliff⁵ has shown also that the streptococci from each of these diseases form distinctive colonies on chocolate agar. On this medium the nondissociating scarlet streptococcus does not produce any changes in color, while streptococci from erysipelas and septic sore throat turn the chocolate agar a vivid green.

As I have mentioned elsewhere,⁶ erysipelas and scarlet fever have been accepted as distinct diseases since scarlet fever was recognized. They do not overlap. Epidemiologically they have nothing in common. There are no records of epidemics in which some patients had scarlet fever, some erysipelas and some both diseases. In 1873 scarlet fever was introduced into the Faroe Islands. For fifty-seven years before, the islands had been free from the disease. In 1873-1875, 38.3 per cent of the population had scarlet fever, but there is no mention of any cases of erysipelas, which would be expected to occur under those circumstances if erysipelas and scarlet fever are caused by the same streptococcus. In rare instances as in Henoch's and Heubner's cases, facial erysipelas has been contracted by physicians and nurses in attendance on patients with scarlet fever. I have not found any good record of the apparent transmission of scarlet fever by erysipelas patients.

The instances in which erysipelas has developed as a complication in scarlet fever are remarkably few. Of 5,416 cases of scarlet fever observed in recent years by Weaver,⁷ six are recorded as complicated with erysipelas, or one in 900. Of 48,366 cases of scarlet fever in the Metropolitan Asylum Board Hospitals in London, 1,094 were complicated with diphtheria, 899 with chickenpox, 703 with measles, 404 with whooping cough, fifty-five with erysipelas (one in 880), eleven with typhoid and one with typhus fever. In 1920 Jenot⁸ reviewed the reports and found that in somewhat more than 50,000 cases of scarlet fever, including the English cases just cited, the complication with erysipelas was many times less frequent than with diphtheria, chickenpox, measles or whooping cough, and of course even far less frequent again than the common secondary streptococcal infections in scarlet fever. As a complication of scarlet fever erysipelas is usually mild and in most cases it develops after convalescence is well under way.

It has been questioned whether scarlet fever can be caused solely by a streptococcus, because, "as a rule, scarlet fever confers lifelong immunity, and it is very rare for the same individual to be attacked twice, whereas streptococcus infections usually increase the

susceptibility with respect to a fresh attack."⁹ This and other doubts about the streptococcal nature of scarlet fever, because it does not correspond closely to other streptococcal diseases, would vanish on acceptance of the view that scarlet fever is caused by a specific streptococcus and is followed by a specific immunity. Right here it should be noted that the immunity to scarlet fever, whether from natural disease or from immunization with toxin, if, as is apparently the case, essentially antitoxic in nature, need not be expected to exclude local and other infections by the scarlet streptococcus either in the course of scarlet fever or independently.

As this matter now stands, it seems quite reasonable to regard scarlet fever and erysipelas, which certainly are distinct clinically, as distinct etiologically also and as caused each by a hemolytic streptococcus. It also seems reasonable to believe that continued work on the problems of streptococcus differentiation will yield new results of interest and practical value.

OBSERVATIONS ON THE CLINICAL COURSE OF CORONARY ARTERY DISEASE

FRED M SMITH, MD

IOWA CITY

HERBERT W RATHE, MD

WAVERLY, IOWA

AND

W D PAUL, MD

IOWA CITY

An inadequate circulation to the myocardium, particularly of the left ventricle, is primarily responsible for the cardiac disability in coronary artery disease. This varies in extent and distribution with the size and number of vessels involved by the sclerotic process and whether they are partially or completely occluded. Moreover, it may develop gradually or occur abruptly as from the sudden closure of one of the larger coronary arteries. In view of the great variation in these and other factors, it is not surprising that the clinical manifestations of coronary artery disease are varied and that sudden death may be the first intimation of the disease in some, whereas others may live for years after the appearance of the first symptom.

This report is based on the study of 420 cases of coronary artery disease in which the progress of the cardiac disability was analyzed with reference to the character of the clinical expression and their significance from the standpoint of further insults to the coronary circulation. In forty-four instances the clinical interpretations were checked by postmortem examination.

These cases were divided into five groups on the basis of the initial or dominant initial symptom, namely, shortness of breath, paroxysmal dyspnea, severe anginal pain, angina of effort and pain in the epigastrium or chest of an indefinite nature. The number in each of these groups and the distribution as to sex is indicated in chart 1.

The following cases are illustrative of each of these groups both with reference to the character of the onset and on the basis of our conclusion concerning the progression of the coronary artery disease

GROUP 1—F M, a man, aged 60, was admitted to the University Hospital, Sept 27, 1932. Shortness of breath first appeared in 1920. The patient was working in a battery station and noticed that he became winded easily when he lifted a battery or crawled under a car. There was no particular change in his condition until the spring of 1923. He then had an attack of severe substernal pain radiating to the left shoulder and down the left arm, which lasted for several hours and required morphine for relief. Following this he became very dyspneic, and edema appeared in the extremities. He was confined to bed for three months. Thereafter he became short of breath rather easily and occasionally had angina of effort. In 1931 he had another attack of precordial pain quite similar to that in 1923. This attack was also followed by congestive failure. There was considerable improvement in the condition but the edema soon returned and the patient presented advanced congestive failure when admitted to the University Hospital.

The heart was very large and there was an auricular fibrillation. The systolic blood pressure was 148 and the diastolic 98. An electrocardiogram showed bundle branch block, auricular fibrillation and frequent premature beats arising from different foci. The patient died on the fifth day following admission.

We believed that this patient undoubtedly had advanced coronary artery disease and concluded that there had been an occlusion of one, and possibly two of the larger vessels.

The heart weighed 850 Gm. There was an extensive sclerosis of the coronary arteries with complete occlusion of the anterior descending branch of the left coronary artery. In addition to the large area of fibrosis resulting from the obstruction of this vessel, scars of varying size but much smaller than the one mentioned, were encountered elsewhere in the myocardium, particularly of the left ventricle.

GROUP 2—L G, a man, aged 65, admitted to the University Hospital, July 20, 1929, had experienced intense dyspnea lasting for more than an hour, in October 1928 after running about a block for a train. Shortly following the recovery from this episode he began to notice shortness of breath. This became more evident in January 1929 and he soon began to have difficulty in sleeping, from paroxysmal dyspnea. He finally reached the stage at which he was compelled to sit up continually. Chest pain of an indefinite nature but never in severe form occurred from time to time and occasionally was transmitted to the left shoulder.

When he was admitted to the University Hospital there was orthopnea and some edema of the lower extremities. The area of cardiac dullness was considerably increased both to the right and to the left. The tones were of poor quality, and an occasional premature beat was heard. The systolic blood pressure was 160 and the diastolic 80. Moist rales were present in the bases of the lungs and the margin of the liver extended about three fingerbreadths below the costal margin. The electrocardiogram showed a bizarre QRS group of low amplitude.

The patient gradually improved and on August 22 was discharged from the hospital. The symptoms, however, soon returned. He was back again in October and finally died from cardiac failure in June 1930, during his third stay in the hospital. During the period of our observation, paroxysmal dyspnea was a prominent feature.

The onset and subsequent course of the cardiac disability pointed to coronary artery disease with occlusion of one of the larger branches in October 1928. The signs of recurring attacks of left ventricular failure dominated the clinical picture until the third admission to the hospital.

The heart weighed 640 Gm. There was an advanced sclerosis of the anterior descending and circumflex branches of the left coronary arteries, with complete occlusion of the former branch. The myocardium of the apical region of the left ventricle was almost entirely replaced by fibrous tissue. Many small scars were found elsewhere in the myocardium of the left ventricle.

GROUP 3—E A, a man, aged 61, admitted to the University Hospital Dec 4, 1928 stated that he was well until a severe

attack of substernal pain ten years before. He recalled that he was very short of breath and, in attempting to walk to the house, fainted. The pain lasted about one hour and required morphine for relief. He was permitted to be up the next day but noticed that he was short of breath for about two weeks. He had no further trouble, however, for four years, or until about six years before admission and in the meantime was able to do the usual work about the farm without any difficulty. While picking corn he was again seized by very severe pain in the chest and shortness of breath. The pain was so severe that he was afraid that he would die before the physician arrived. Following this, edema of the feet and legs developed. This disappeared during a period of two weeks in bed. Thereafter he became short of breath rather easily and every few months was compelled to go to bed for a period of rest. In October 1928 the breathlessness increased and the edema became more marked.

There was generalized anasarca when he was admitted to the University Hospital. The heart was very large and the cardiac tones were distant and poorly differentiated. A musical systolic murmur was heard over the apical region. The rhythm was that of auricular fibrillation. The systolic blood pressure was 144 the diastolic 70. Electrocardiogram showed a partial bundle-branch block and auricular fibrillation.

The patient did not respond to treatment and died after several months in the hospital. We concluded that he had had an occlusion of two of the larger coronary arteries. The first occurred in 1918 and the second in 1922. He withstood the first attack without any significant lasting impairment in the cardiac function, as evidenced by the fact that he was able to do the

Chart 1—Coronary artery disease. Initial symptoms in 420 cases. A shortness of breath B paroxysmal dyspnea C severe anginal pain D angina of effort E indefinite pain

usual work on a farm for a period of four years or until the second coronary occlusion.

The heart weighed 625 Gm. The right coronary artery and the anterior descending branch of the left coronary artery were completely occluded a short distance from their origin.

GROUP 4—A K., a man, aged 50, admitted to the University Hospital, June 9, 1930, was apparently in good health until an automobile accident in August 1929. He was badly shaken up by the accident and required several weeks for recovery. In November 1929 he began to notice substernal pain with certain physical activities and excitement. This gradually progressed and when we first saw him the history was typical of angina of effort. The results of the examination of the heart were entirely negative aside from a rather tall T wave in leads 2 and 3 and a prominent Q wave in lead 3 of the electrocardiogram.

The condition improved somewhat but he continued to have an occasional attack of pain. In May 1931 the pain began one evening while the patient was sitting quietly on his porch. It soon became very severe, lasting until the next day, and repeated administration of morphine was required before complete relief was obtained. The pain, according to the patient, was identical in every respect to that of his previous attacks of angina of effort except that it was more severe and more lasting. The patient was confined to bed for twelve days. Three days later he had a cerebral accident followed by weakness of the right arm. This was the occasion for the second admission to the hospital, June 26, 1931.

There was at this time some shortness of breath and the heart was definitely increased in size. The cardiac rate was increased, the sounds were of poor quality and a gallop rhythm was noted. The systolic blood pressure was 102, the diastolic 74. Striking

alterations had occurred in the electrocardiogram. The amplitude of the QRS group was greatly reduced and the duration increased. There was a sharply negative T wave in leads 2 and 3, with some alteration in the RT segment of all leads. The shortness of breath disappeared during the two months stay in the hospital, but the persistence of the elevated cardiac rate and the gallop rhythm pointed to an extensively damaged heart. During this time there was very little change in the electrocardiogram.

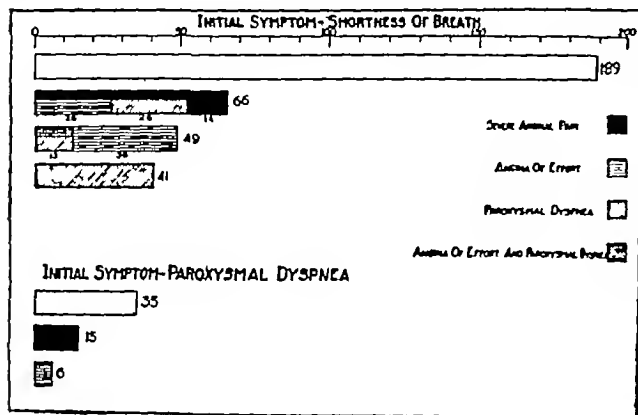

Chart 2—Subsequent course

Within a few weeks after his discharge from the hospital the shortness of breath returned and soon paroxysmal dyspnea appeared. The patient was again admitted to the hospital, Dec. 27, 1931, and died a few days later from a pulmonary embolus.

When the patient was examined in 1930 there was no evidence of structural changes in the heart except as suggested by alteration in the electrocardiogram. The history, however, indicated the presence of a sclerosis of the coronary arteries. The severe attack of pain in May 1931 and the subsequent course justified the diagnosis of the occlusion of one of the larger branches of the coronary arteries resulting in extensive change to the myocardium.

The heart weighed 460 Gm. There was an extensive sclerosis of the coronary arteries. The anterior descending branch of the left coronary artery was completely occluded, resulting in the formation of a large area of fibrosis involving the apical region of the left ventricle, the interventricular septum and a small section of the right ventricle. Scattered areas of fibrosis were encountered elsewhere throughout the myocardium of the left ventricle.

GROUP 5—L. W., a man, aged 67, admitted to the University Hospital, Jan. 14, 1931, stated that for the past three years he had been troubled with gas on the stomach. In October 1929 he was run over by a car passing over his lower ribs and epigastrium. He was in bed for five weeks. Following the accident there was a progression of the indigestion, and in August 1930 definite pain was noted. Later the pain extended up on the chest and was accompanied by a sensation of pressure. The day before admission to the hospital the patient was taken with a more severe attack of pain, lasting all night. There was still some distress when he was admitted to the hospital the following afternoon. The later appearance of a pericardial friction rub and the occurrence of characteristic alterations in the electrocardiogram verified the diagnosis of coronary occlusion. The patient was retained in the hospital for six weeks and when discharged was free from cardiac symptoms.

The distress in the beginning was very indefinite and confined for the most part, if not entirely, to the epigastrium. Later, however, the extension to the chest, the associated feeling of constriction and finally the coronary occlusion established the diagnosis of coronary artery disease.

In the first group the shortness of breath frequently persisted for months and often for years before further evidence of an impaired cardiac function developed. The onset in group 2, classified as paroxysmal dyspnea,

was characterized by the sudden appearance of intense dyspnea in an individual who previously had been free from cardiac symptoms. These attacks often occurred at night but in many instances appeared during the day following some form of exertion. They might last for several hours and were invariably followed by a reduction in the exercise tolerance or other symptoms directing attention to the heart. In group 3, in which the dominant initial symptom was severe anginal pain, the severity and duration of the pain and the subsequent course were such that one would not hesitate to make the diagnosis of coronary occlusion. The same criteria relative to the character and significance of this particular manifestation was adhered to in the analysis of the subsequent course of this series of cases except in those under observation when other information was available. Group 4, beginning with angina of effort, included only those patients whose history was in every respect typical of the disorder. Those patients in whom there was doubt concerning the nature of the pain were placed in group 5. In many of them the discomfort was confined for the most part to the epigastrium.

The subsequent developments in groups 1, 2, 3 and 4 are indicated in charts 2 and 3. The later course of group 5 indicated that the pain was anginal in nature from the onset and consequently these patients were later included in group 4. It is to be noted that shortness of breath on exertion was the initial symptom in 189 (59 per cent). The subsequent course in this group was of particular interest to us. One might expect that a large percentage of these patients would gradually pass into congestive failure, but our analysis shows that in 156 (82 per cent) the further progression of the cardiac disability was evidenced by either angina of effort, attacks of severe anginal pain (indicating a coronary occlusion), paroxysmal dyspnea or a combination of these manifestations. Pain was a prominent feature in that it occurred in 115 (60 per cent). In sixty-six (34 per cent) it was on the basis of coronary occlusion, whereas in forty-nine (25 per cent) it was

Chart 3—Subsequent course.

that of angina of effort. When these patients were later seen by one of us or admitted to the hospital, 107 (56 per cent) presented congestive failure, usually in an advanced form. Pain, however, was still rather conspicuous, since twenty-one sought medical advice primarily because of angina of effort and twenty because of the immediate or later effects of coronary occlusion.

The clinical course of the other groups was quite similar to that of the foregoing, varying only in the incidence of the different manifestations. In the group with the onset of severe and prolonged pain, forty-

seven (52 per cent) had subsequent attacks of a similar character. Angina of effort and paroxysmal dyspnea were likewise prominent in the subsequent course of the patients in this group. Even in the group in which the onset was with paroxysmal dyspnea, fifteen (43 per cent) later had attacks of severe chest pain characteristic of coronary occlusion.

The composite clinical picture presented by groups 2, 3 and 4 were still quite similar to that of group 1 when the patients were admitted to the hospital (chart 4).

Chart 4—Cause of admission to hospital. A, shortness of breath; B, paroxysmal dyspnea; C, severe anginal pain; D, angina of effort.

There was a higher incidence of congestive failure in groups 2 and 3. Pain was still a prominent manifestation in groups 3 and 4.

Eighty-five of this series of patients died while in the hospital and forty-four came to necropsy. The clinical analysis and the postmortem observations with reference to the coronary arteries are shown in chart 5. The clinical study justified the diagnosis of an occlusion of one or more of the larger branches in twenty-six instances. At necropsy there was in every instance a disseminated fibrosis from the occlusion of smaller branches, and in twenty-eight one or more of the larger vessels were obstructed. In the two in which the occlusion of one of the larger branches was not diagnosed before death the onset was with paroxysmal dyspnea, and in one specific mention was made in the record to the effect that the patient had never had substernal pain.

COMMENT

In the analysis of the foregoing series of cases the intimate relationship between angina of effort, severe anginal pain (coronary occlusion) and paroxysmal dyspnea was one of the outstanding features. Either of these manifestations might occur alone in the beginning of the cardiac disability, but sooner or later they were commonly combined to a varying extent in the same individual. This would indicate that these manifestations were merely different expressions of the same basic factor, namely, a deficiency in the coronary circulation.

The data in chart 3 show that, in the group in which the onset of the cardiac disability was initiated by a coronary occlusion, approximately 50 per cent later gave a history of angina of effort. The incidence of angina of effort was also high in the other groups following a coronary occlusion. Moreover, in the group in which the initial symptom was represented by angina of effort, fifty-seven (54 per cent) subsequently had an attack of very severe pain indicative of an obstruction of one of the larger vessels. It is well to recall that before the identification of the syndrome of coronary occlusion the latter was included in the description of angina pectoris. In recent years there has been a tendency to lose sight of what Parkinson¹ has referred

to as the essential unity of angina pectoris and coronary occlusion. It is believed that we are justified in assuming that angina of effort, particularly in the type of case under consideration, is generally indicative of a deficiency of the coronary circulation. In many instances the deficiency in the circulation responsible for the angina results from the obstruction of a larger vessel. The same condition, in our opinion, often follows the closure of smaller branches. A more detailed analysis of certain of our cases in which at first the angina of effort was apparently the initial symptom disclosed a history very suggestive of coronary occlusion. The first attack of pain in these particular patients was either more severe and lasting than the subsequent attacks or occurred under unusual circumstances for angina of effort, such as while the individual was at rest and completely relaxed. Further support of this is provided in many by the occurrence of a sharply negative T wave, a prominent Q wave or perhaps a broad and bizarre QRS group in the electrocardiogram. This conception has a significant bearing on treatment, for if these occlusions are recognized and therapy is directed toward the restoration of the coronary circulation it is possible that the angina of effort may be prevented or postponed.

The relationship between coronary occlusion and paroxysmal dyspnea is as intimate as that of coronary occlusion and angina of effort. These conditions, likewise, may occur independently or be combined in the same individual. In the typical case of coronary occlusion, pain is the outstanding feature and often there is surprisingly little dyspnea. In others, however, even though the pain is severe and lasting, the dyspnea is a conspicuous aspect of the clinical picture. Finally, there is a smaller group in which the dominant symptom is that of intense air hunger. While there is usually a varying degree of tightness or heaviness of the chest,

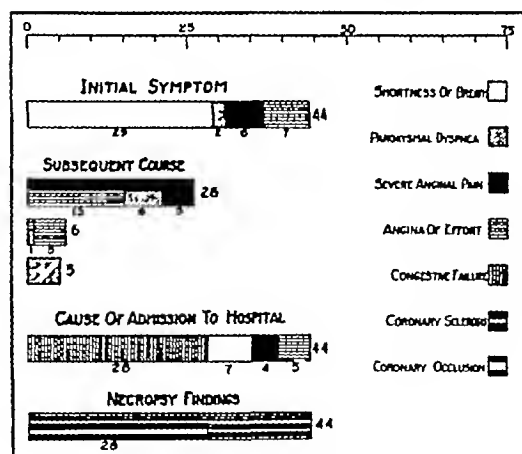

Chart 5—Necropsy cases

the respiratory distress far overshadows that of pain. These attacks constitute what is generally known as paroxysmal dyspnea (cardiac asthma). They are indicative of an abrupt and profound disturbance in the function of the left ventricle or acute left ventricular failure.² When paroxysmal dyspnea occurs as the initial manifestation of a cardiac disability in coronary artery disease it is invariably dependent on a sudden

Cardiac Asthma (Paroxysmal Dyspnea) and the Syndrome of Left Ventricular Failure. *J A M A* 100: 1841 (June 10) 1933.

and extensive reduction in the coronary circulation, as from the obstruction of one of the larger coronary vessels. It appeared as the initial symptom in thirty-five (85 per cent) of our cases. Two of these later came to necropsy and the heart in each showed a large healed infarct. In the group beginning with shortness of breath the subsequent progression of the cardiac disability was evidenced by the appearance of paroxysmal dyspnea in forty-one (21.5 per cent). This type of clinical manifestation, as will be noted in our cases, occurred commonly during the later stages of the coronary artery disease regardless of the character of the onset. At this stage the functional efficiency of the left ventricle may be so reduced that temporary failure is readily precipitated. Under these circumstances, however, the appearance of paroxysmal dyspnea may mean a further reduction in the coronary circulation in many instances perhaps through the closure of a small vessel. In certain of our cases this possibility was supported by the occurrence of consecutive alterations in the electrocardiogram.

It is well to bear in mind that the coronary circulation is frequently capable of compensating to a remarkable extent to the major insults incident to a sclerotic process. In the first place it is generally known that an advanced sclerosis of the coronary arteries may be present without cardiac symptoms. Furthermore, an individual may live for years after the onset of symptoms. We have recently observed a patient in whom the angina of effort first appeared seventeen years before his death at 74 years of age. During the past few years he had experienced many attacks of severe and lasting pain pointing to the possibility of repeated coronary occlusion. At necropsy there was a complete occlusion of the anterior descending branch of the left coronary artery and extensive sclerosis of the other main branches. In addition to the large scar from the obstruction of the anterior descending branch of the left coronary artery, the left ventricle presented numerous smaller areas of fibrosis. These changes illustrate in a striking manner the remarkable adaptability of the coronary circulation in this particular instance. There are numerous instances in the literature on angina of effort of patients living from ten to fifteen, and a few even twenty years or more after the onset of the disorder.³ Many if not all of these no doubt had had coronary occlusion not necessarily, however, involving one of the main branches. White and Bland,⁴ in discussing the prognosis of angina of effort, state that coronary occlusion was frequently encountered in their series of cases but that it did not affect appreciably the duration of life, provided the patient survived the acute attack. The duration of the cardiac disability in our series of cases from the time of onset until seen by us ranged from a few weeks to twenty years. In eighty-five (20 per cent) the cardiac disability dated back five years or longer. According to our clinical interpretation, 311 (74 per cent) of our series had had an occlusion of one of the larger coronary vessels. Of these, we believe that there were 105 in which more than one of the larger branches were occluded. Furthermore, the history of many of these patients indicated that they withstood their attack and later had a fairly

efficient heart, even though they were permitted to be up and about the next day or were allowed this privilege within a few days following the coronary accident.

While an individual may withstand the occlusion of one of the larger coronary arteries and live for years afterward, even though he may have received little or no treatment except perhaps morphine for the control of the pain, the aftercare is commonly the deciding factor in determining the extent of the resulting cardiac disability. This may mean the difference between an irreparably damaged heart and one in which the subject is free from symptoms. The results from rest and therapy directed toward the restoration of the coronary circulation are occasionally striking even after the development of congestive failure. Any significant progression of the cardiac disability in coronary artery disease is generally dependent on further damage to the coronary circulation. If this is borne in mind and the patient is treated accordingly, much may be accomplished toward conserving the cardiac function.

SUMMARY

A series of 420 cases of coronary artery disease was analyzed with particular reference to the character and significance of the clinical manifestations. These cases were divided into five groups on the basis of the initial or the dominant initial symptom, namely, shortness of breath, paroxysmal dyspnea, severe anginal pain, angina of effort, and pain of an indefinite nature. The subsequent developments were quite similar and varied only in the incidence of the different manifestations. In the vast majority, further progression of the cardiac disability was evidenced by either angina of effort, attacks of severe anginal pain, paroxysmal dyspnea or varying combinations of these. The intimate relation of these clinical manifestations was one of the outstanding features in the progression of the cardiac disability in this series of cases. This would indicate that they are merely different expressions of the same basic factor, namely, a deficiency of the coronary circulation.

The attacks of severe anginal pain were typical of coronary occlusion. According to our analysis, 311 (74 per cent) of our cases presented an occlusion of one or more of the larger coronary vessels. In the forty-four cases that came to necropsy there was an obstruction of one of the main branches in twenty-eight. These pathologic changes were predicted in twenty-six, and in all there was a history of an attack of severe anginal pain. Angina of effort commonly follows a major coronary accident, and it is believed that it is frequently precipitated by the obstruction of smaller branches. The occurrence of paroxysmal dyspnea as the initial manifestation of a cardiac disability, particularly in the type of case under consideration, is invariably dependent on the abrupt closure of one of the larger coronary vessels. Subsequent attacks or those occurring during the later course of coronary artery disease may mean a further reduction in the coronary circulation, possibly in many instances through the obstruction of the smaller branches.

The coronary circulation frequently shows remarkable ability in compensating for the insults incident to a sclerotic process. The extent of the resulting cardiac disability, however, is greatly influenced by treatment. It is thus important that the possibility of further damage to the coronary circulation is considered whenever there is a significant progression of the cardiac disability and that the patient is treated accordingly.

THE DIFFERENTIAL DIAGNOSIS IN
PATIENTS ENTERING THE
HOSPITAL IN COMAPHILIP SOLOMON, M.D.
AND
CHARLES D. ARING, M.D.
BOSTON

In the year 1933, 1,167 patients, or 3 per cent of the total hospital admissions, entered the Boston City Hospital in coma. The size of this figure is startling and certainly is greater than is generally appreciated. Since there are many causes of coma which require emergency treatment to save life, for example, diabetes, hyperinsulinism, poisoning, traumatic shock, exsanguination, subdural hematoma, brain tumor, meningitis and eclampsia, the importance of immediate diagnosis is evident.

Textbook articles on coma¹ discuss the subject in a general and abstract way without special regard to the practical problems involved. The literature in the journals² is on the whole subject to the same criticism, although a few authors³ have attempted to aid the practitioner in the diagnosis of coma of unknown cause. In no case, however, have the actual conditions found in comatose patients been analyzed with the purpose of obtaining information of practical diagnostic value.

The records of the 1,167 admissions in coma to the Boston City Hospital in the year 1933 have been analyzed, and the frequency of the various causes for coma has been previously reported.⁴ The present paper is a critical analysis of these causes with the purpose of determining criteria of use in the diagnosis of coma. The various conditions that produced coma in our 1,167 cases are discussed in their order of frequency. A large proportion of these cases were seen by one or the other of us in our capacity as neurologic consultants.

CONDITIONS PRODUCING COMA

Alcoholism (690 cases, 59.1 per cent of total cases of coma, mortality in this group 2 per cent).—Individuals under the influence of alcohol are brought to the City Hospital from all parts of the city, usually by the police ambulance. There were 2,079 admissions for alcoholism (6 per cent of the total admissions) in

the year 1933. Six hundred and ninety of these 2,079 cases, or 33 per cent, were admitted to the hospital in coma. The records of most of the alcoholic patients are inadequate, and the data regarding alcoholic coma are therefore subject to error. Many reentries are included in this group.

Usually a history of alcoholism was obtained, not on entry but later. The typical patient had a flushed face, injected throat and conjunctivae, diminished or absent reflexes, and an alcoholic odor to the breath. Minor injuries about the head were present in 11 per cent of our 690 cases and minor injuries elsewhere about the body in 2 per cent. Vomiting was common, and convulsions occasionally occurred. Laboratory examinations were negative. In the fatal cases the coma was usually more complete from the outset, and convulsions were more common. In these cases the physical examination was likely to show some further abnormality such as cyanosis, enlarged heart, heart sounds irregular or of poor quality, pulmonary râles, low blood pressure, high blood white cell count or non-protein nitrogen.

The chief diagnostic features of alcoholic coma were the alcoholic odor to the breath, the hyperemia of the face, throat and conjunctivae, and the absence of other abnormalities.

Trauma (152 cases, 13 per cent of total cases of coma, mortality in this group 31.5 per cent).—A history of trauma was available on entry in more than 90 per cent of these cases. Seven per cent of the patients were under the influence of alcohol at the time the trauma occurred. Three per cent were epileptic patients injured in a convulsion. In children, a history of vomiting following the accident was considered important as probably signifying increased intracranial pressure. Injury to the head was the cause of the coma in 90 per cent in this group, while chest, pelvis and spinal cord injuries made up the remaining cases. Among the patients with head injuries, twelve had a subdural and three an extradural hemorrhage.

In the physical examination, evidence of injury was present in every case. Serious prognostic signs were compound fracture of the skull, bleeding or drainage of cerebrospinal fluid from the nose or ear, and signs of surgical shock. In one third of the cases there was some abnormality in temperature, pulse or respiration, the usual conditions observed being a low temperature and high pulse and respiration. In one fourth of the cases the pupils were abnormal. Significant neurologic signs were present in the cases of brain or spinal cord injury. In 43 per cent of the patients with head injuries a fractured skull was demonstrated by roentgen examination. By lumbar puncture bloody cerebrospinal fluid was obtained in sixty-two cases, and in forty-two the pressure of the fluid was increased.

The diagnosis of traumatic coma was not difficult, because of the history of accident and the evidences of injury on examination. In the further differentiation of the type of injury, roentgenograms and lumbar puncture were helpful. The differential diagnosis between a contusion or laceration of the brain and an extradural or subdural hemorrhage may be very difficult. This subject has been fully discussed recently by Munro.⁵

Cerebral Vascular Lesions (118 cases, 10 per cent of total cases of coma, mortality in this group 77 per cent) —The history in these cases was valuable. In 49 per cent the onset was known to be abrupt. Other helpful points in the history were onset with convulsions, previous high blood pressure or heart disease, and previous "shocks" or "strokes." The age of the patient was important. More than 90 per cent were over 40 years of age, and 75 per cent were over 50. The following signs were present on entry: complete or partial hemiplegia in 57 per cent, stiffness of the neck in 13 per cent, convulsions during the examination in 9 per cent, temperature increased in 9 per cent, temperature decreased in 31 per cent, respirations increased in 24 per cent, and abnormalities in respiratory rhythm in 30 per cent. The blood pressure was elevated in 50 per cent of the cases, the pupils were abnormal in 70 per cent. The physical examination occasionally showed abnormalities in the heart, lungs, eyegrounds, pulse, Babinski's toe sign and Kernig's leg sign. Cyanosis was not uncommon and peripheral edema was rarely present. The urine was abnormal in thirteen cases, and the Kahn test of the blood was positive in six. Of the seventy-eight patients in this group who had a lumbar puncture, forty-three had a high pressure and forty-two had grossly bloody fluid.

The clinical diagnoses, arrived at before discharge, of the 118 cases in this group were: cerebral hemorrhages 35 per cent, cerebral thrombosis 33 per cent, cerebral embolus 4 per cent, and primary subarachnoid hemorrhage 3 per cent. In 18 per cent the data in the records were not sufficient to make possible a differential diagnosis as to the type of cerebral vascular lesion. Of the five cases of cerebral embolus, four showed auricular fibrillation and one a severe rheumatic carditis. The four cases of primary subarachnoid hemorrhage gave no evidence of a focal cerebral lesion but presented a grossly bloody cerebrospinal fluid. Two of these patients had stiffness of the neck, and a history was given of an abrupt onset of headache in the other two. The differential diagnosis between the various types of cerebral vascular lesions has been discussed by Aring and Merritt⁶.

The most important points in the diagnosis of coma due to cerebral vascular lesions were the history of sudden onset of the coma, the age of the patient, the presence of a hemiplegia, and an increased blood pressure or auricular fibrillation. The lumbar puncture of a bloody fluid under an increased pressure was of great aid in the diagnosis of intracerebral or subarachnoid hemorrhage.

Poisoning (thirty-three cases, 3 per cent of total cases of coma, mortality in this group 9 per cent) —The history of attempted suicide was frequently obtained in cases of coma due to acute, nonalcoholic poisoning. In sixteen of these cases the history of ingestion of barbitol or its derivatives was obtained. Twelve patients had been exposed to carbon monoxide, deliberately or accidentally, in a garage or because a gas stove had blown out. In the five remaining cases, a history was obtained of the ingestion of one of the following drugs: bromide, potassium permanganate, nitrobenzene, compound solution of cresol, and sodium nitrite.

The physical examination and laboratory data in the patients in the barbitol group were usually normal. After these patients awoke, which usually occurred

within twenty-four to forty-eight hours, they frequently had for a few days slurred speech, nystagmus, tremor of the hands, and absent tendon reflexes. Rarely a skin rash appeared. There was one fatality in this group.

The patients with carbon monoxide poisoning were usually in light coma and had a strong odor of illuminating gas on their breath. When given a mixture of oxygen and carbon dioxide to breathe, they often recovered consciousness quickly. The face sometimes had the characteristic bright "cherry red" color. The temperature was uniformly subnormal and the pulse high. The tendon reflexes were frequently increased, Babinski's toe sign was positive, and rarely decerebrate rigidity was present. The white blood cell count was usually increased. Lumbar puncture was done in three cases. The initial pressure was 200 mm of water in one but was well within normal limits in the other two. There were no abnormalities in the spinal fluid. Spectroscopic examination of the blood gave the characteristic absorption bands of carbon monoxide in two cases and in two cases did not. There were no fatalities in this group.

The patient with bromide poisoning had an increased amount of bromide in the blood and spinal fluid. The patient with potassium permanganate poisoning had potassium permanganate in the vomitus and stomach washings. The patient with compound solution of cresol poisoning had burns of the mouth and face, and there was the characteristic odor of compound solution of cresol in the vomitus and stomach washings. This patient died. The patient who ingested sodium nitrite had an ashen gray cyanosis with purplish black lips and tongue, a high blood hemoglobin, and on spectroscopic examination the blood contained methemoglobin. The patient who took nitrobenzene died in shock.

The history was the most important point in the diagnosis of coma due to nonalcoholic poisoning. Of importance also was the odor of the breath, the odor, appearance and chemical analysis of the stomach washings, and, in carbon monoxide poisoning, the "cherry red" color of the skin and subnormal temperature.

Epilepsy (twenty-eight cases, 24 per cent of total cases of coma, mortality 0) —The history on entry of the abrupt onset of the coma preceding or accompanying a convulsion was obtained in all but one of these cases. In three, excessive alcoholism preceded the attack. In most of the cases in this group, a history of repeated seizures in the past was obtained. Thirteen of the patients had convulsions while being examined. Two patients were in status epilepticus, with high temperature and increased cardiac and respiratory rates. Fresh lacerations, frothing at the mouth, and old scars on the tongue were present in six cases. Babinski's toe sign was positive in four cases. The physical examination was otherwise not remarkable.

The diagnosis of coma following an epileptic convulsion was made on entry in almost every case on the basis of the history obtained from friends or relatives accompanying the patient. The occurrence of convulsions during the physical examination, and wounds or scars on the tongue were of assistance in establishing the diagnosis.

Diabetes (twenty cases, 17 per cent of total cases of coma, mortality in this group 55 per cent) —Diabetic coma is not yet rare. Of the twenty cases in this series, three represent the same patient on different admission. In thirteen cases a history of diabetes was

⁶ Aring, C. D. and Merritt, H. H. The Differential Diagnosis Between Cerebral Hemorrhage and Cerebral Thrombosis. Arch. Int. Med., to be published.

obtained on entry. There had been recent dietary indiscretions in four, a recent infection of the upper respiratory tract in three, and boils in three. In one case, in which diabetes had not been previously diagnosed, a history was obtained of recent polydipsia and an increased fondness for sweets.

On examination the following signs were noted: temperature elevated in four (associated with an infection) and subnormal in ten; pulse increased in seventeen, respirations increased in nine, Küssmaul breathing in eleven, shallow breathing in one, eyeballs abnormally soft in seven and normal in two, acetone on the breath in fourteen, throat inflamed in nine, dehydration in fifteen, and moist râles at the lung bases in four. The urine showed the presence of sugar in every case, the white blood cell count was increased in seven, and the red cell count was high in one case. The blood non-protein nitrogen was 102 mg per hundred cubic centimeters in one case associated with dehydration. The blood sugar was high in fifteen cases, was normal in one, and, after insulin, was low in one. A lumbar puncture was done in one case, and the initial pressure was found to be zero. (This finding of decreased intracranial pressure parallels the decreased intra-ocular pressure, both being part of the picture of dehydration.)

The diagnosis of diabetic coma was strongly suggested by the history on entry in more than half the cases in this group. Physical changes of diagnostic significance were subnormal temperature, increased pulse, Küssmaul respirations, soft eyeballs, acetone on the breath, and dehydration. Laboratory observations of diagnostic importance were glycosuria and hyperglycemia.

Meningitis (twenty cases, 17 per cent of total cases of coma, mortality in this group 100 per cent) —It is not generally realized that meningitis is as common a cause of coma among hospital entrants as diabetes. Of the cases reported here, ten were of children under 10 years of age. There was a history of injury in four. Important symptoms in the history were vomiting ten cases, convulsions nine cases, infection of the upper respiratory tract eight cases, fever seven cases, headache six cases, mental disturbance five cases, ear trouble five cases, stiff neck three cases, chills two cases, exophthalmos associated in two cases with sinus thrombosis, and in one case each abdominal pain, diplopia, and paralysis of an arm. In the past history there was tuberculosis in one patient, another was a nursing infant whose mother had active tuberculosis, one patient had recently picked a pimple on his nose, another had just been operated on for cataract.

On examination the temperature was high on entry in most of the cases, and the pulse and respirations were increased. There was acetone on the breath in one case. Choked disks were present in three cases. Although stiffness of the neck was the rule, it was absent in three cases on entry. There was redness of the throat in six cases. The Kernig leg sign was positive in eleven cases, negative in six, and not mentioned in three. The Babinski toe sign was positive in seven cases, negative in three and not mentioned in ten cases. In three cases a bulging fontanel was observed. Opisthotonos was present in one case. Roentgen studies of the chest in two cases demonstrated miliary tuberculosis, in one advanced tuberculosis and in one lobar pneumonia. The white blood cell count was high in five cases and normal in six. The blood culture was positive for pneumococci in three cases and for staphylococci in

one. Lumbar puncture gave results of paramount importance, the spinal fluid being grossly abnormal in every case in which it was examined. A lumbar puncture was not performed in four cases. The spinal fluid pressure was increased in twelve, normal in one and not recorded in three cases. Xanthochromia was present in two cases. All the fluids were purulent. The cellular content was recorded in thirteen, eight of which contained more than 1,000 white cells per cubic millimeter. Organisms were found on examination of stained smears of the sediment in seven cases. Cultures of the fluids were positive in ten cases: pneumococci in seven cases, and streptococci, staphylococci and meningococci in one case each. The spinal fluid sugar was found to be low in twelve cases, the chlorides were low in ten cases, and the protein was high in eleven cases.

In the diagnosis of meningitic coma, the age incidence was of importance, since half the patients were children under 10 years of age. Symptoms pointing to infection about the head, increased intracranial pressure or meningeal irritation were significant in the history. Valuable diagnostic physical signs were fever, stiffness of the neck, positive Kernig's leg sign and Babinski's toe sign, and a bulging fontanel in infants. The spinal fluid was grossly abnormal in every case in which it was examined. The white cells and protein in the spinal fluid were increased and the sugar and chloride decreased. In most cases organisms were found either by smear or by culture.

Pneumonia (twenty cases, 17 per cent of total cases of coma, mortality in this group 90 per cent) —Pneumonia is not mentioned in textbooks as one of the diagnoses to be considered in cases in which coma is a presenting sign. Yet pneumonia is as common as diabetes, and three times as common as uremia in this series. The majority of cases in this group appeared in the young and very old. Four patients were under 10 years of age and eleven over 50, of whom four were over 70. The onset of coma was abrupt in four cases, but in two of these it was associated with alcoholism. In two of the children a history was obtained of convulsions in the present illness. Other significant data available in the histories were cough in five cases, fever in three cases, "cold" in two cases, and sudden pain in the side, bloody sputum, chill, abdominal pain, vomiting and diarrhea in one case each. In nine cases no history was available. On examination, the temperature was elevated in fourteen cases and subnormal in two (in each of these two cases death occurred within four hours). The pulse was increased in fifteen cases, the respiration in eleven. Cyanosis was noted in twelve cases. In all cases in which the chest was examined, signs of consolidation were found. In two patients the lungs were not examined, presumably because the patients were considered alcohol addicts. In two cases, death occurred before a complete examination could be made. An acidotic breath was noted in three cases, hiccups in two, abdominal distention in two, jaundice and an enlarged liver in one, a positive Babinski's toe sign in one. A white blood cell count was done in ten cases, being increased in two and normal in eight. A red blood cell count was low in three cases, the non-protein nitrogen of the blood was normal in two cases and high, but below 100 mg per hundred cubic centimeters, in five cases. Lumbar puncture was done in six cases, but no abnormality was found.

Coma as a presenting sign due to pneumonia was more common in the young and very old and was

case In four cases, lumbar puncture was done The initial pressure was high in two cases and normal in two The nonprotein nitrogen of the spinal fluid was very high in the three cases in which it was examined, and the chlorides of the spinal fluid were high in two cases

In the cases of uremic coma, a history of previous kidney trouble, high blood pressure, convulsions or recent infections was occasionally obtained The helpful physical signs were muscular twitchings, acetone on the breath, abnormal eyegrounds, enlarged heart, increased blood pressure, and edema of the ankles Important laboratory changes were gross abnormalities in the urine, and increased nonprotein nitrogen of the blood

Eclampsia (seven cases, 0.6 per cent of total cases of coma, mortality in this group 68.4 per cent) —A history of pregnancy was obtained in every case, of convulsions in six cases of vomiting in five, of headache in three, of high blood pressure in one and of swelling of the extremities in one The women were, of course, in the child-bearing age Pregnancy was obvious by examination of the abdomen in every case Other manifestations were rapid pulse, in every case, convulsions in six, blood pressure increased in six and decreased in one (this patient succumbed within eight hours), edema of the extremities in six, and fever in three The urine was grossly abnormal in every case, the white blood cell count increased in two, the nonprotein nitrogen of the blood was slightly increased in one A lumbar puncture was done in two cases The initial pressure was increased in one and was normal in the other

In the patients entering the hospital in eclamptic coma, a history of pregnancy was always obtained In most cases a history of convulsions and vomiting was also given The diagnostic physical signs were abdominal tumor, rapid pulse, convulsions, peripheral edema and increased blood pressure The urine was grossly abnormal in every case

Miscellaneous (forty-eight cases, 4.1 per cent of total cases of coma, mortality in this group 75 per cent) — There were many uncommon causes of coma massive hemorrhage, ten cases (cause trauma four cases, spontaneous rupture of esophageal varix two cases, carcinomatous erosion in the gastro-intestinal tract two cases, ruptured aortic aneurysm one case, massive hemoptysis one case), burns four cases, erysipelas four cases, encephalitis three cases, brain tumor three cases, miliary tuberculosis two cases, carcinomatosis two cases, and one each of hypoglycemic shock, Stokes-Adams disease, immersion, syncope, hysteria, pernicious anemia, leukemia, ruptured ectopic pregnancy, intestinal obstruction, gangrene of the periurethral tissue and abdominal wall due to rupture of membranous urethra, cholemia, empyema and septicemia In seven cases the cause of the coma could not be determined One of these was a patient with Simmond's disease, and one was a patient with Friedreich's ataxia The chief significant points in the differential diagnosis of the miscellaneous cases are included in the following discussion

COMMENT

The importance of the history in the early diagnosis of coma as a presenting sign cannot be overstressed Table 1 lists the points in the history which were of special diagnostic value Table 2 lists the physical changes that were outstanding in their diagnostic value

The age of the patient was of interest, since the degenerative conditions (cerebral vascular lesions, cardiac decompensation and uremia) occurred chiefly among elderly patients, while infectious conditions (meningitis and pneumonia) were more frequent in the young The laboratory data were often the deciding points in the diagnosis Table 3 illustrates the most helpful laboratory observations

It should be noted that little emphasis has been placed on the depth of the coma, the condition of the pupils or the state of the reflexes In our cases these have not been of great practical differential value The depth of the coma may vary, no matter what the cause The pupils tend to be abnormal in the majority of the cases of coma, regardless of the cause, and there is no definite rule as to what kind of abnormality will be present in any particular case The same is, in general, true of the reflexes Gowers⁷ has pointed out that the manifestations in a patient in coma depend to a large extent on the depth of the coma, whatever the cause

TABLE 3—Laboratory Observations Helpful in the Diagnosis of Coma and the Conditions in Which They Occur

Lumbar puncture					
Pressure					
Increased	cerebral vascular lesions of the central nervous system	meningitis	trauma	syphilis	
Decreased					diabetes
Bloody fluid			cerebral vascular lesions		trauma
Purulent fluid					meningitis
Organisms by smear and culture					meningitis
Sugar					
Low					meningitis

					cardiac decompensation
					heart block
					cardiac decompensation

may be This has been our experience If the coma is light, the reflexes may be preserved and may be hyperactive, perhaps because of release of the lower centers by lack of cerebral control Automatic swallowing may be preserved, and the pupils may still react to light Painful stimuli may elicit muscular movements As coma deepens, the depressed condition of the higher centers spreads to the lower Reflexes become diminished or absent, swallowing becomes impossible, the pupils fail to react to light, the body musculature becomes flaccid, and myotatic irritability may be lost The palatal muscles may share in this relaxation and, moved by the respiratory current of air, may cause the peculiar stertor that is a familiar indication of the depth of the coma Even the respiratory center may become depressed, so that respiration is decreased, shallow and irregular The lessened respiratory movements fail to clear the air passages of the secretion, which accumulates in the bronchi and finally in the trachea, causing the familiar "rattle" that is popularly and rightly recognized as a frequent harbinger of death

⁷ Gowers W R A Manual of Diseases of the Nervous System London J & A Churchill 2 99 1893

It should be pointed out that there are many other causes for coma that are not included in this discussion, for example, sunstroke, electrical shock and acute pancreatitis. These conditions are sufficiently rare, however, so that no patient entered the Boston City Hospital in coma in the year 1933 with such a diagnosis.

SUMMARY

In 1,167 cases of coma as a presenting sign, the data available on admission to the hospital, including history and physical and laboratory observations, have been analyzed with a view to determining the characteristic features of diagnostic importance in each of the various causes of the coma. The material is arranged in the order of the relative frequency of the various causes, and a summary of the most practical diagnostic characteristics is appended under each cause. In the discussion, the differential diagnosis is considered and the most significant points in the history, physical examination, and laboratory changes are tabulated. It is noted that the depth of the coma, condition of the pupils and state of the reflexes are not of great diagnostic importance.

PERIPHERAL NEURITIS CAUSED BY PROLONGED USE OF DINITROPHENOL

J. ERNEST NADLER, M.D.
NEW YORK

The number of cases of poisoning by alpha-dinitrophenol has greatly increased in the past year. This is due to the fact that the drug is now frequently used either alone or as a constituent of certain preparations for reducing weight. Notwithstanding the considerable number of cases of poisoning that have been reported, there still remain many points for consideration in the study of this drug. For this reason it seems justifiable to report instances of poisoning in the hope that, from a larger mass of more diversified observations, facts of direct importance regarding these mooted points may be obtained.

This report deals primarily with late or delayed poisoning by dinitrophenol. The cases here detailed are believed not to be unusual but to present a condition not hitherto described, so far as the relation of the cause and its effects are concerned. As has been stressed by Quick,¹ too little emphasis has been given to the possibility that a drug such as dinitrophenol may have an indirect or latent effect. Repeated warnings have been given, particularly against its use in patients with a history of arthritis.² It has long been known that chronic intoxication by benzene,³ dinitrobenzene,⁴ dinitrotoluene⁵ and trinitrotoluene⁶ may cause neuritis.

From the Department of Therapeutics, New York University College of Medicine and the Third (New York University) Medical Division of Bellevue Hospital.

It would therefore not be surprising if dinitrophenol, which is so closely chemically related to these substances, should also possess this toxic feature.

This report is based on the study of twenty-two persons who took alpha-dinitrophenol (1-2-4). Fifteen were seen in private practice and the remainder in the wards of Bellevue Hospital. Sixteen showed no deleterious effects from the use of the drug, of the remaining six cases, in three a rash developed, in one loss of taste and in two peripheral neuritis. The six patients showing toxic symptoms were taking the drug for obesity and gave a negative history for allergy, neuritis, arthritis, alcoholism, diabetes, tuberculosis, or liver or kidney disease.

The symptoms of acute poisoning with dinitrophenol are too familiar to require detailed description here, so only brief mention will be made of them. In one woman, weighing 110 Kg. and taking 0.1 Gm. of dinitrophenol a day, a markedly pruritic rash developed on the eighth day, similar to those previously described.⁷ The drug was immediately stopped and the rash disappeared in five days. She was very anxious to resume taking the drug, even though she was cautioned that the rash might return.⁷ Tainter and his associates⁶ maintain that the use of the drug may be resumed with impunity after the skin reaction has subsided. Five days later she again took 0.1 Gm. a day and in two days the rash reappeared. The drug was stopped and the condition cleared up rapidly. In another woman, weighing 69 Kg., after taking 0.1 Gm. a day for eight days a similar eruption developed, the drug was stopped and the rash cleared up in two days. In the third patient, weighing 80 Kg., taking 0.1 Gm. three times a day, a rash developed on the twenty-first day. She lost 13 pounds (5.9 Kg.) during this period. Coincident with the eruptions all these patients complained of weakness in the legs and rheumatoid pains in the arms and fingers.^{2b} These symptoms promptly disappeared after the drug was stopped.

Loss of the sense of taste as a result of intoxication by dinitrophenol has been reported by Tainter, Stockton and Cutting⁶ and by Jackson and Duvall.⁸ We had one patient in whom this developed after she had been taking the drug for thirty-six days. This loss was complete for "sweet," "sour," "salt," and the like, and she experienced a "coppery" taste in her mouth at all times. She was not anesthetic to epirritic and protopathic stimuli, i. e., to light touches, pin pricks and temperature. The sense of smell was unimpaired. The drug was not stopped and her taste gradually returned to normal in a month.

The two cases in which what we believe to be a peripheral neuritis developed following prolonged use of this drug will be reported in some detail. In presenting these cases we are fully aware of the important role played by vitamin B deficiency in the production of peripheral neuritis. These patients were on a diet containing adequate amounts of the vitamin B complex.

REPORT OF CASES

CASE 1—D. M., a white woman, aged 33, married, a housewife, with a past medical and family history which was negative for any condition that might contraindicate the use of alpha-dinitrophenol, was given a drug for the purpose of reducing weight. She was 63 inches (160 cm.) tall, weighed 87 Kg. and had a basal metabolic rate of +1 per cent. Dec. 7, 1933, she was given 0.1 Gm. once a day, and as she showed no sensitivity

⁷ Frumess G. M. *Allergic Reactions to Dinitrophenol* J. A. M. A. 102: 1219 (April 14) 1934.
⁸ Jackson Harry and Duvall A. I. *Dinitrophenol Poisoning* J. A. M. A. 102: 1844 (June 2) 1934.

to the drug after ten days it was increased to 0.1 Gm three times a day. There was no excessive sweating or other untoward symptom until March 8, 1934, at which time she stated that her toes felt numb. Her weight at this time was 78 Kg. The drug was continued. The numb feeling in her toes persisted and on March 29 (weight 75 Kg) she started to experience spontaneous tingling, "pins and needles," dulness and itching of the toes. A careful search was made for a local cause of this particular dysesthesia, whether in the skin, muscles, bones, joints or blood vessels. Pain was not due to local disease, nor was it continuous or accompanied by objective phenomena such as redness of the skin, swelling or tenderness of the tissue or rigidity of the joints and so on. The sense of position was unimpaired and there was no decrease in the vibratory sense or finer coordination of the toes. There was a slight increase of the patellar reflexes. The patient never had an elevation of temperature.

April 12 (weight 73 Kg) she complained of slight arthritic pains in the left hand, and, as she was developing marked hyperesthesia of the toes to touch, the drug was stopped. Ordinary stimuli evoked an unusual sensation, as for example a feeling of tingling when the skin was touched and a feeling of acute pain when moderate cold was applied. No local pallor as seen in the early stages of cutaneous angioneuroses, edema, or increase in sweating of the affected parts was observed. These paresthesias persisted and fleeting pains developed in various joints. April 30, in addition to the toes, the ankles, left wrist and the fingers of both hands were painful. The joints were normal on examination. The arthritic pains did not respond to salicylates and amidopyrine. By May 8 there was considerable improvement in the joint pains but exacerbations occurred with changes in the weather. At the present writing, nine months after the onset the arthritic pains have entirely disappeared but some numbness and tingling of the toes persists.

The innumerable possibilities of diagnosis were gradually reduced as the study of the symptoms proceeded, until it seemed that but one theory, namely, peripheral neuritis, could be held to explain the acroparesthesia and arthralgia.

CASE 2.—A white woman, aged 56, a housewife, who was 62 inches (157 cm) tall, weighed 80 Kg and had a basal metabolic rate of -5 per cent, had moderate arteriosclerosis, with essential hypertension of 192 systolic, 120 diastolic. She exhibited no sensitivity to the drug, so after ten days she was put on 0.1 Gm of alpha-dinitrophenol three times a day. Thirty-six days later she lost her sense of taste (previously described). Her weight at this time was 70 Kg and the blood pressure 170 systolic, 90 diastolic. The drug was continued and her taste gradually returned to normal on the seventy-third day (weight 64.5 Kg, blood pressure 178/98). Twelve days later (weight 60 Kg, blood pressure 178/98) she stated that all her toes were numb and felt dead, as if they did not belong to her. In view of the experience in the previous case the drug was immediately stopped. No local cause for the sensory disturbances could be found. The course was very similar to that in case 1 except that the patient experienced more pain in the joints of the toes and was more annoyed by the hyperesthesia.

The moderate peripheral sclerosis present in this case may have been a contributing factor. I believe that the loss of the sense of taste in this patient may be part of the neuritic picture and therefore should be considered as a form of chronic poisoning in contrast to the dermatitis. Outside of the slight discomfort in the toes, both patients feel better now than prior to taking the drug. The blood pressure in the first case was not affected, and in the second case it dropped from 192/120 to 170/90, at which level it persisted for about two months after the drug was stopped before returning to its original level.

This delayed toxic effect of dinitrophenol is not due to accumulation of the drug in the body, for it is rapidly destroyed and eliminated.^{2a} A tolerance for this drug

is rapidly established in animals.⁹ The effects noted are most likely due to the repeated attacks of therapeutic amounts of the drug in certain individuals who are unpredictably sensitive to dinitrophenol.¹⁰

SUMMARY AND CONCLUSIONS

1 Of twenty-two persons taking dinitrophenol, symptoms of poisoning developed in six in three a pruritic rash, in one loss of taste, and in two peripheral neuritis.

2 The cases of multiple peripheral neuritis showed very striking sensory symptoms but no motor or trophic disturbances. The condition starts in the toes and exhibits various disturbances of sensation, such as prickling, numbness and pain.

3 Paresthesia persists long after its original cause has been removed.

4 This delayed poisoning is due to repeated exposure to small amounts of dinitrophenol and not to an accumulation of the drug in the body.

FUNCTIONAL CHANGES IN LIVER, HEART AND MUSCLES, AND LOSS OF DEXTROSE TOLERANCE

RESULTING FROM DINITROPHENOL

CYRIL M. MacBRYDE, MD

AND

BARRETT L. TAUSSIG, MD
ST. LOUIS

A short time after the appearance of the first clinical report on the use of dinitrophenol,¹ we began a series of studies of its effects in producing weight loss in obese patients. It seemed important to determine whether the metabolic stimulation produced by the drug was accompanied by evidence of injury to the patients.

Dinitrophenol first came to the attention of the medical profession as an industrial poison.² Although during the World War poisoning of those working with it in munitions plants was frequent,³ physicians and drug manufacturers, undeterred by the early history of the drug, have brought about a tremendous usage during the past year. One clinic has supplied to physicians, or to patients on physicians' prescriptions, over 1,200,000 capsules of 0.1 Gm each, corresponding to about 4,500 patients treated with the drug in one year. More than twenty wholesale drug firms are marketing the compound.⁴

As was to be expected, numerous reports of toxic actions have appeared. Skin reactions, consisting of maculopapular dermatitis, urticaria or angioneurotic-like swelling, usually accompanied by burning sensations and pruritus, and sometimes by desquamation, have been frequent.⁵ Evidence of renal damage has been reported in two cases.⁶ In three patients liver damage has apparently been produced.⁷ Five deaths have been reported from the use of the drug and one from the closely related compound dinitroresol. Of the six deaths, three have occurred with known overdosage.⁸ The other three occurred in patients taking amounts within the so-called therapeutic range of from 3 to 5 mg per kilogram of body weight.⁹ Two of these deaths followed the development of malignant neutropenia. Severe neutropenia with recovery has occurred in four other cases in which excessive doses were not given.¹⁰ Physicians have been encouraged to minimize these evidences of toxicity on the ground that unpredictable idiosyncrasies can account for them.⁴

Our studies reveal that dinitrophenol causes notable clinical variations in the functions of the liver, heart and muscles and a loss of dextrose tolerance in patients who have displayed no evidence of special sensitivity.

METHODS OF STUDY

Liver function was tested by the determination of the icterus index after the serum was decolorized with dilute hydrochloric acid, by the van den Bergh reaction on the serum, by the estimation of urobilinogen in the urine, by the galactose tolerance test, and by the quantitative estimation of phenoltetraiodophthalein retention after intravenous injection. The technique of the study of liver function with this dye and the results in various types of liver disease have been described by Cole, Copher and Graham.¹¹

The tests of renal function consisted of repeated examination of the urine for albumin, red cells, white cells and casts, concentration-diuresis tests with measurement of the specific gravity, phenolsulphonphthalein excretion and blood nonprotein nitrogen determinations.

Effects on the circulatory system were studied by frequent records of the pulse rate and blood pressure, frequent auscultation, electrocardiographic tracings, and 6-foot roentgenograms of the heart with measurement of the cardiac shadow. The respiratory rate was also counted several times a day.

Exercise tolerance tests, urinary excretion of creatine and creatinine, urinary phosphate excretion and estimation of blood lactic acid were studied as possible indexes of functional changes in the muscles.

Dextrose tolerance was estimated by giving the patients orally 0.8 Gm of dextrose per pound of body weight and determining the sugar in the capillary blood (by Somogyi's method¹²), after one-half hour, one hour, two hours and three hours.

Frequent measurements of the morning resting fasting metabolic rate were made in all cases. The type of fuel was studied by measurement of the nitrogen excretion in the urine and by determination of respiratory quotients before and after a standard test meal. The Hagedorn apparatus was employed.¹³

* After omission of drug for period of fourteen days.

Those cases studied in Barnes Hospital were under the constant observation of the trained staff of the Turill Metabolism Ward, the diets being accurately regulated and material for chemical determinations promptly collected and measured. All patients, whether studied in the hospital or outpatient department, were observed closely and frequently to detect skin rashes. All the patients were obese women between 22 and 56 years of age. The amount given was in each case 0.1 Gm of alpha-dinitrophenol three times daily.

RESULTS

Liver Function.—Six out of eight patients showed an increased dye retention after dinitrophenol medication (table 1). Normal dye retention at the end of thirty minutes is between 10 and 15 per cent. In two patients receiving the drug for seven days there was a rise from 10 to 24 per cent and from 12 to 19 per cent respectively. In one patient receiving the drug for fourteen days, retention increased from 14 to 28 per cent. In three patients after twenty-one days of medication there were rises from 10 to 17, from 13 to 20 and from 14 to 21 per cent respectively. Two of these patients received the drug for eight weeks with retentions of 17 and 18 per cent at the end of that time. The dinitrophenol was then omitted for two weeks and the liver function tests were repeated. Fifteen per cent was retained in both cases. This is the upper limit of nor-

mal, the control readings before use of the drug having been 10 and 13 per cent. In two patients there was practically no change in the ability to excrete the dye after taking dinitrophenol.

No significant variations in the corrected icterus index, the serum van den Bergh, the urinary urobilinogen or the galactose tolerance tests were noted. This may not be surprising, since these tests are believed to measure either very extensive liver damage or obstruction to bile excretion. In the estimation of liver damage in the absence of biliary obstruction or very severe hepatic injury, dye excretion tests may be the more sensitive criteria.¹⁴

In 1918 Warthin¹⁵ reported the first pathologic study of a fatal case of dinitrophenol poisoning in this country. An acute degenerative hepatitis similar to that resulting from chloroform, arsenic, phosphorus, trinitrotoluene and acute yellow atrophy was the chief finding. One of the main effects of dinitrophenol experimentally has been the rapid depletion of liver glycogen.¹⁶ The importance of an adequate glycogen store in the liver as a protection against toxins has been much emphasized.¹⁷ Trinitrophenol (picric acid), trinitrotoluene and other compounds closely related to dinitrophenol are notorious liver poisons. It is therefore not surprising to find evidence of liver damage, even with the small doses and short periods employed in our study.

Kidney Function—No changes were noted in the urinary sediment, in the blood nonprotein nitrogen or in the kidney function tests in three patients studied in the hospital over a period of eight weeks.

Circulatory System—There were no significant alterations in the pulse rate, blood pressure, respiratory rate or cardiac auscultation in six patients, each studied in the hospital for from six to eight weeks. These observations correspond with those of others.

Three of our patients, however, showed definite alterations in their electrocardiograms. In one patient's record there occurred a marked increase in size of the T wave in the first two leads, an inversion of the T wave in lead 3, and a depression of the ST interval in lead 2. In the second case there was an increase in the size of the T waves, depression of the ST interval and moderate notching of the QRS complex. In the third, inversion of the T wave in lead 3 and left axis deviation developed. These changes in all three cases began to appear at the end of the second week and were more marked toward the end of the eight weeks of medication. Two of the patients showed persistence of the changes after the drug had been omitted for two weeks.

Somewhat similar effects in two patients and in four of six experimental animals have been reported by de Châtel and Motika.⁶ In two of the fatal human cases, fragmentation of the heart muscle has been found at postmortem examination.¹⁸ The electrocardiographic changes may be early signs of toxic damage to the heart.

Muscle—Marked fatigue is one of the most evident effects of dinitrophenol medication. Exercise tolerance tests in four patients revealed considerable loss of strength and endurance. These four patients received creatine-free diets of 1,100 calories, and daily determinations were made of the urinary creatine and creatinine.

After a control period of one week dinitrophenol medication was begun. In two, urinary phosphate and nitrogen were also determined daily. In each of the four

cases there was a rise in creatine excretion. In two the creatinine rose slightly, in one it fell and in one it was essentially unchanged. The total creatine-creatinine excretion rose in three. Urinary phosphate rose during the first week or two, then tended to return to the control level. The results are summarized in tables 2 and 3. There was a rise in the blood sugar in all four cases, and blood lactates were slightly increased in two.

Shorr, Richardson, and Wolff,²³ in studying the muscle weakness of hyperthyroidism, found certain biochemical similarities to progressive muscular dystrophy. They concluded that the high metabolism of hyperthyroidism overtaxes the processes maintaining the integrity of the phosphocreatine mechanism and that the muscle weakness of exophthalmic goiter is of the nature of an acute muscular dystrophy. A somewhat similar

† After omission of the drug for a period of fourteen days.

disturbance of muscle metabolism would explain the marked weakness occurring after metabolic stimulation with dinitrophenol.

Experimental studies of Tainter and Cutting²⁴ showed the liver and muscles to be the chief sites of action of the drug. Recent studies of increased muscle metabolism²⁵ indicate that the oxidation of lactic acid formed from glycogen, the formation of hexosephosphate from glycogen and phosphocreatine, and the hydrolysis of phosphocreatine are the fundamental biochemical processes in the increased energy production. Recovery is accompanied by resynthesis of phosphocreatine, and resynthesis of lactic acid and hexosephosphate to the glycogen from which they were derived. When normal recovery is prevented, a marked decrease in muscle glycogen and phosphocreatine, an increase in muscle and blood lactates, and an increase in the elimination of dextrose, phosphate and creatine should be expected.

Evidence of prevention of recovery with actual loss of muscle substance as a result of dinitrophenol medication would seem to be offered by our clinical and biochemical studies and by the experimental studies of others.²⁶

Dextrose Tolerance—Blood sugar curves following dextrose tolerance tests showed a definite increase in the elevation of the curve in nine out of twelve cases.

The loss of tolerance was evident after seven days and increased in degree with the duration of administration and with the total dose given (table 4). The type of diet had no influence on the susceptibility to this change. In cases 2, 5 and 6 the rate at which dextrose was removed from the blood was essentially unchanged. No patient showed an increased ability to utilize dextrose. There is, of course, considerable variation possible in successive blood sugar curves on the same patient. The fact that the chief factor causing such changes, namely, alterations in diet, has been eliminated makes it significant that all the differences encountered were in the direction of loss of tolerance.

One patient with diabetes showed a progressively higher curve while receiving the drug for four weeks. The impaired tolerance persisted after discontinuance of the medication, so that the insulin dosage on the same control diet had to be increased. Two patients in a prediabetic state showed loss of tolerance. In one of these tolerance had not returned to the control level after omission of dinitrophenol for two weeks. In one nondiabetic patient who had received the drug for fourteen days, tolerance had not returned to normal two weeks after it had been stopped.

Magne, Mayer and Plantefol,¹⁶ observing great decreases in muscle and liver glycogen, concluded that the increased oxidation with dinitrophenol depended chiefly on the combustion of carbohydrate. It has been suggested²⁷ that dinitrophenol might possibly be of use in increasing carbohydrate utilization in diabetes. Our

observations fail to support this supposition, since the diabetic as well as the nondiabetic patients showed decreased sugar tolerance. We did not observe any evidences of increased toxicity in diabetic patients. Special susceptibility might have been expected, since in diabetic dogs its toxicity is greatly increased.²⁸

The high metabolic rate of hyperthyroidism is frequently accompanied by diminished sugar tolerance and by a reduction of liver glycogen, attributed by some observers to a fault in glycogenesis. A similar mechanism may explain the diabetogenic action of dinitrophenol. However, the persistence of the decreased tolerance long after the drug has been discontinued and the metabolic rate has returned to normal suggests impairment of insulin production. The action of exogenous insulin was unchanged in two of our cases, indicating that the hyperglycemia was not due to any directly insulin-resistant factor²⁹ but possibly to a reduced insulin supply.

Fuel Burned—The metabolic rates rose within twenty-four hours after the first ingestion of the drug and remained at a level between plus 30 and plus 70 per cent as long as it was continued. In two patients receiving the drug over a period of four weeks there was no rise in urinary nitrogen (table 3). In three the respiratory quotients during the use of the drug were slightly lower than in the control period. This was true both of the determinations made while fasting and of those following a standard test meal containing protein, fat and carbohydrate (table 5). Accordingly, we must conclude that both carbohydrate and fat, but not protein, serve as fuel for the increased oxidation and that the principal nutrient oxidized is fat. These results are in essential agreement with those obtained by Hall and his co-workers.¹⁰

Miscellaneous Results—In all, fifteen patients were studied, six over prolonged periods in the hospital and nine in the outpatient department. No case of neutropenia occurred. Three patients had quite severe skin rashes. Five patients had gastro-intestinal disturbances with repeated vomiting. One experienced practically a complete loss of the sense of taste, lasting for several weeks after discontinuance of the drug. All the patients complained of greatly increased perspiration, loss of appetite and weakness. Fluid intake was increased and urine output greatly diminished. On diets of approximately 20 calories per kilogram of body weight, the weight loss averaged from 1½ to 2½ pounds (680 to 1,135 Gm.) per week. On diets of 11 calories per kilogram the loss increased to from 2 to 4 pounds (900 to 1,800 Gm.) weekly. In some instances the weight loss was a pound or more a day and could be demonstrated to be due chiefly to fluid loss by perspiration.

SUMMARY

Dinitrophenol in small doses caused functional changes indicative of toxicity in liver, heart and muscles in a large percentage of patients in whom no special idiosyncrasy was noted. It also produced a loss of dextrose tolerance.

Only two of the five deaths that have been reported have occurred with overdosage. Three have followed doses within the so-called therapeutic range. Six cases of severe neutropenia have occurred, two of them fatal. These and other toxic manifestations have been attributed to special susceptibility.

The fact that the majority of our patients showed somewhat alarming functional changes emphasizes the question whether the use of a drug with so great potential dangers is justified in the treatment of a relatively benign condition such as obesity.

THE NATURE OF THE PRECEDING INFECTION IN ACUTE GLO- MERULONEPHRITIS

IN TWO NEW YORK HOSPITALS AND IN
FOUR SOUTHERN HOSPITALS

DAVID SEEGAL, M.D.
BEATRICE CARRIER SEEGAL, M.D.
AND
JOHN D. LYTTLE, M.D.
NEW YORK

A previous paper¹ has shown that the reported hospital medical admission rate for acute glomerulonephritis is similar in four latitude regions of the United States and southern Canada. In contrast, there is a diminished case frequency for scarlet fever and rheumatic fever in the South as compared with the North. Since clinical and laboratory evidence favors the hypothesis that acute glomerulonephritis is chiefly related to a preceding hemolytic streptococcus infection, it appeared peculiar that the diminution in incidence of the hemolytic streptococcus diseases scarlet fever and rheumatic fever in the southern latitudes did not also occur in the group of patients with acute nephritis. Osman,² who studied the data on deaths from acute and chronic nephritis compiled from tables in the League of Nations International Year Book for 1928, found it impossible to correlate the figures with climatic or racial factors.

In order to gain more accurate information concerning the geographic incidence of acute glomerulonephritis and the type of infection predisposing toward it, a comparative study of the hospital records of acute glomerulonephritis has been made over a period of years in the Presbyterian and Babies hospitals in New York, the Touro Infirmary, New Orleans, the John Sealy Hospital, Galveston, Texas, and the Baylor and Parkland hospitals, Dallas, Texas. The records for these hospitals have been reviewed for the following years: Presbyterian Hospital, 1917 through 1933, Babies Hospital, 1930 through 1933, Touro Infirmary, 1927 through 1932, John Sealy Hospital, 1920 through 1932, Baylor Hospital, 1927 through 1932, Parkland Hospital, 1928 through 1932.

The cases of acute glomerulonephritis have been selected in these various institutions on the basis of the clinical history, the physical examination, the laboratory data and the course of the disease. In many instances the cooperation of the physicians in the respective hospitals was the determining factor in the selection of cases with questionable diagnosis. Case histories were excluded from this group, which on study showed that the underlying condition was not acute glomerulonephritis of the type unequivocally agreed on by clinicians. Such histories were examples of disease better classified in one of the following categories: (a) postoperative renal suppression, (b) renal shutdown due to such agents as prostatic hypertrophy and

From the Departments of Medicine of Bacteriology and of Diseases of Children, Columbia University College of Physicians and Surgeons and the Presbyterian Hospital and Babies Hospital.

This study was made possible by the generous cooperation of Dr. John H. Musser and his associates at the Tulane University Medical School, Dr. I. L. Lemann of Tulane University and the Touro Infirmary, Dr. Arthur Vidrine, Dean of the University of Louisiana Medical School, Dr. Paul Cameron of the Louisiana State University Medical School, Dr. Henry M. Winans of Baylor University Medical School and Dr. Charles T. Stone of the John Sealy Hospital.

malignant metastasis, (c) bacterial endocarditis, (d) poisoning by such agents as mercury and arsphenamine, (e) hypertensive cardiovascular disease, (f) nephritis due to arteriosclerosis, and (g) nephrosis

When the histories of those patients believed to have had true acute glomerulonephritis had been finally selected, it was found that, in the periods studied, there were 152 cases at the Presbyterian Hospital,

previous observations³ on this point, it is noted that about half the cases occur before the age of 11 years and 70 per cent appear before the age of 21

SEX INCIDENCE

Chart 2 shows the sex incidence in the two groups of cases studied. The values for the North and South are almost identical and illustrate that the incidence of acute glomerulonephritis is about twice as frequent in the male as in the female. Osman³ has shown that the preponderance of males over females affected by this disease is significant in every age group except that from 16 to 20 years.

SEASONAL INCIDENCE

Chart 3 shows that acute glomerulonephritis in the northern hospitals studied is chiefly a disease of the late winter and early spring, the high points being in February, March and April. In this period hemolytic streptococcus disease reaches its peak in the North. The curve for the seasonal incidence of acute nephritis in the South is much flatter than that for the northern hospitals. The high rates occur in January and February with a depression of the rate from March through July and a secondary rise in August. The explanation for the increase in the frequency in January to February may be dependent on the early onset of spring in the South.

NATURE OF THE PREVIOUS INFECTION IN ACUTE GLOMERULONEPHRITIS

A study was made of the type of preceding infection in the histories analyzed. There were a number of cases in the southern hospitals in which available data gave no information as to the presence or absence of a

Chart 1—Age incidence in acute glomerulonephritis

sixty-six cases at the Babies Hospital and 163 cases, about equally divided, in the southern hospitals. There were, therefore, 218 cases in the New York hospitals for comparison with 163 cases in the southern hospitals.

It was possible to determine an approximate census for the medical hospital admissions in the New York hospitals as compared with those in the South, despite the difficulties related to the inclusion of a dermatologic or a neurologic unit in the medical service of one hospital, whereas another hospital might have one of these services as an independent unit. The figures for the hospital medical admissions, while not entirely accurate, showed that in the periods studied there were approximately 34,918 medical admissions in the four southern hospitals and 35,000 medical admissions in the two northern hospitals.

On the basis of the data thus collected, the incidence for acute glomerulonephritis in the northern hospitals was 0.62 per cent, that for the southern hospitals was 0.47 per cent. It was found, however, that in one of the southern hospitals it was customary each year for from seven to nine cases of frank acute glomerulonephritis to be studied in the outpatient department for blood chemistry values alone. These patients were not admitted to the hospital but were referred home for treatment by the private physician. Such histories could not be included in the records studied in this paper. Despite the elimination of these cases, the incidence of acute nephritis is very much the same in these northern and southern hospitals.

AGE INCIDENCE

Since acute nephritis is a disease chiefly of childhood and early adult life, it was felt necessary to compare the age groups in the two latitude areas studied in order that this possible source of error might be avoided.

Chart 1 shows the percentage age incidence of the northern and southern cases of acute nephritis at different age periods. It is seen from this graph that the number of cases in each age classification is approximately the same for the two groups. Confirmatory of

Chart 2—Sex incidence in acute glomerulonephritis.

preceding infection. There was no definite statement in this group of histories ruling out the fact in question.

Chart 4 illustrates the incidence in percentages of all the infectious prodromes in the cases of acute nephritis in the North and in the South. In many instances, individual case histories recorded multiple infections such as acute tonsillitis and acute cervical lymphadenitis. Since it is common knowledge that such infections as cervical lymphadenitis, otitis media

and acute mastoiditis are usually associated with a preceding pharyngitis, it was considered advisable to select the most significant single one of the infections noted. For example, if in a patient's history it was found that sore throat, otitis media and mastoiditis had been present, mastoiditis was selected as the chief infection preceding the onset of acute nephritis. This method was obviously inaccurate, but, since the same method was used in the study of the northern and the southern cases, it is believed that the results are comparable.

Chart 3—Monthly incidence of acute glomerulonephritis. Percentage of cases in southern and New York hospitals. (Since two of the New York patients were admitted twice for acute glomerulonephritis the figure 220 is used instead of 218.)

It would seem from chart 4 that the same type of infection precedes the onset of acute glomerulonephritis in both northern and southern patients. Every type of prodromal infection noted in the records has been included in this chart. It is probable that if more data were available in the 22 per cent of the southern cases classified as "data for preceding infection neither positive nor negative" the variations between the two comparative groups would not be as large as the chart depicts. In the northern and southern groups there are only 7.8 per cent and 6.4 per cent of cases respectively in which a preceding infection has been definitely denied.

Lohlein⁴ in 1907 stated that the vast majority of cases of acute glomerulonephritis followed a streptococcal infection. Longcope, O'Brien, McGuire, Hansen and Denny⁵ reviewed the facts on the subject collected by Volhard and Fahr, Hill and others and have reached a similar conclusion. Their bacteriologic and immunologic studies strengthen this opinion. Osman⁶ showed that infection of the upper respiratory tract was the outstanding prodromal feature in acute glomerulonephritis. In 1928 Rake⁷ stated that "99 per cent of cases of nephritis follow a streptococcal infection."

The chart shows that the type of preceding infection in both groups is for the most part that which is presumably caused by the hemolytic streptococcus. In a large number of our cases there is evidence of a deep infection by the hemolytic streptococcus. Prominent among such types of pathologic changes are cervical lymphadenitis, peritonsillar abscess, otitis media and mastoiditis.

It is surprising to note the relatively minor role played by scarlet fever in initiating acute glomerulonephritis in this series of cases. Murphy, Grill and

Moxon⁸ have recently concluded that "scarlet fever can no longer be looked upon as the chief cause of glomerular nephritis."

In addition to the series of infections presumably due to the hemolytic streptococcus, the case histories show that in a small percentage of the cases the attack of nephritis has been preceded by an inflammatory process due to the pneumococcus or staphylococcus. The studies of Neale⁹ and Blackman and Rake¹⁰ and others would lend support to the conception that the pneumococcus may initiate the syndrome of acute nephritis in children. In our series there are seven cases of acute glomerulonephritis in adults apparently related to a preceding pneumococcal infection. Evidence for a concomitant hemolytic streptococcus infection in this group is absent. A discussion of the problem is given in a previous paper.¹¹

COMMENT

A previous paper¹ contains a comparative study of the geographic distribution of rheumatic fever, scarlet fever and acute glomerulonephritis in North America. The admission rates for rheumatic fever and acute glomerulonephritis were determined in twenty-four hospitals distributed throughout the United States and southern Canada. The figures for scarlet fever were obtained from the standard public health reports, and the conclusions were based on the statistical studies of Schroeder and Longacre.¹² It was deduced from these facts that although the case frequency of scarlet fever and rheumatic fever was lower in the southern latitudes than in the northern latitudes, the yearly medical hospital admission rate for acute glomerulonephritis did not vary significantly in the four latitude regions studied.

Chart 4—Type of preceding infection in acute glomerulonephritis. Percentage of cases in southern and New York hospitals. Only the single most pronounced infection is shown for each patient.

In order that the problem might be studied with more accurate data, the individual case histories of patients with acute glomerulonephritis have been reviewed in two northern and four southern hospitals. The results of this investigation have shown that the case frequency is about the same in these two groups.

of hospitals. This parallelism does not depend on age or sex factors. It has been shown furthermore that the type of preceding infection is similar in the two groups of cases. The conclusions drawn in the previous paper are therefore confirmed by the more accurate data available in this study.

Despite the fact that acute glomerulonephritis appears to be as frequent in the selected group of southern hospitals as in the northern hospitals and that the preceding infection in both regions seems to be one chiefly related to the hemolytic streptococcus invasion, it has been shown that the case frequency in the South for the known hemolytic streptococcus disease scarlet fever and the probable hemolytic streptococcus disease rheumatic fever are diminished as compared with the North. This observation would suggest that, if all three diseases are related to a preceding hemolytic streptococcus infection, there must be factors other than a specific hemolytic streptococcus to account for the lack of parallelism between the geographic distribution of these three diseases.

CONCLUSIONS

1 The case histories of 216 cases of acute glomerulonephritis at the Presbyterian and Babies hospitals in New York City have been compared with 163 case histories of the same disease distributed at the John Sealy Hospital, Galveston, Texas, the Touro Infirmary, New Orleans, and the Baylor and Parkland hospitals, Dallas, Texas.

2 In the years studied there were approximately 35,000 admissions to the medical wards in the two groups of hospitals.

The medical admission rate for acute glomerulonephritis was 0.62 per cent in the northern hospitals and 0.47 per cent in the southern hospitals. Allowing for a variation in the admission rules at the various hospitals, the case frequency of the disease in the two groups of hospitals is closely parallel.

3 The age groups of the northern and southern cases are similar. About 50 per cent of the cases occurred before the age of 10 years, 70 per cent before the age of 21.

4 In both groups of cases the disease is almost twice as frequent in the male as in the female.

5 The type of infection preceding the bout of acute glomerulonephritis is much the same for the two groups. The form of the infection is that which is usually associated with tissue invasion by the hemolytic streptococcus. Many of the patients in both groups manifest a deep infection such as acute cervical lymphadenitis, peritonsillar abscess, otitis media and acute mastoiditis. Other preceding infections noted were chiefly those due to the pneumococcus and the staphylococcus.

6 The data in a previous paper¹ showed that, although the reported medical admission rate for acute glomerulonephritis was similar in twenty-four hospitals in four latitude regions, the case frequency for two other diseases chiefly of hemolytic streptococcus origin, scarlet fever and rheumatic fever, was less in the South than in the North.

The aggregate evidence suggests that, if scarlet fever, rheumatic fever and acute glomerulonephritis are incited by the hemolytic streptococcus, other factors in addition to a common specific bacterium must exist to account for the lack of parallelism between the geographical distribution of the three diseases.

SIMMONDS' DISEASE (PITUITARY CACHEXIA)

REPORT OF A CASE IN WHICH THE PATIENT
RESPONDED TO ANTERIOR PITUITARY-LIKE
PRINCIPLE OF PREGNANCY URINE

L. F. HAWKINSON, M.D.
BRAINERD, MINN.

Simmonds¹ originally described the entity of pituitary cachexia in 1914. More than fifty cases were reported in the German literature from 1914 to 1933. The first cases reported in the American literature were by Graham and Farquharson² in 1931.

The disorder is due to a disturbance of the anterior lobe of the pituitary. Various processes, including tumors, cysts, emboli, thrombosis, trauma, tuberculosis and syphilis, have been held responsible for the disturbance in this portion of the gland.

The common misconception still exists that pituitary disorders are due solely to tumor or some other organic disease of the gland. While in many cases previously reported the disease has been accompanied by gross pathologic changes in this organ, Engelbach³ maintained that many pituitary cachexias, as well as other forms of pituitary dysfunction, may be due to a transitory functional disorder of the anterior lobe. He thought it probable that severe deficiencies of the hypophysis occur as frequently from aneoplastic disorders as from other causes. This fact is corroborated by many writers and further by the effect of substitution therapy in a number of cases with excellent results.

The syndrome has been noted in several cases following repeated labors, especially when they are accompanied by hemorrhage. Maresch⁴ first called attention to this fact and suggested that a functional exhaustion of the anterior pituitary was a basis for the etiology in these cases. A hereditary factor has been suggested by several writers, and there is considerable evidence that this may have been a factor in a number of cases.

Clinically, these cases have been characterized by weakness, emaciation, mental lethargy, somnolence, premature aging, trophic changes in the skin, loss of pubic and axillary hair, low metabolic rate, hypotension and disturbances of sexual functions, including amenorrhea.

The onset is insidious, and the syndrome may develop in from a few months to several years. The disease is progressive and if untreated the prognosis is exceedingly grave. The course, however, may run over a considerable period. Oppenheimer⁵ has observed a patient with this disorder over a period of twenty years.

Emaciation is the most striking feature, and the cachexia usually exceeds that found in other conditions. Loss of weight is constant, and losses of from 50 to 60 pounds (23 to 27 Kg.) are common. Weakness follows the loss of weight with a concomitant loss of sexual function. In women, amenorrhea is often the first symptom noted. The recession of the secondary sex characters is a late feature. Mental symptoms are common. These may be so severe that the patient is first seen by the psychiatrist. Mental lethargy and somnolence are rather constant symptoms. The loss

- 5 Oppenheimer, B. S. in discussion on Graham and Farquharson.

of pubic and axillary hair is a characteristic feature. Loss of eyebrows and eyelashes has also been noted by a number of writers.

The basal metabolic rate is consistently depressed and a finding of from minus 25 to minus 30 per cent is not uncommon. A case in which the basal metabolic rate was minus 40 per cent has been reported by Brougher.⁶ This finding tends to confuse the disorder with primary hypothyroid states, some of which are also attended by cachexia.

Premature aging is not an early feature but one that appears after the syndrome is well established. Hypotension is always present, and there is usually a bradycardia. Anemia is a frequent finding and the leukocyte count is often low. Eosinophilia is occasionally encountered.

Various other features have been present in many cases. The most common of these are disturbance of carbohydrate metabolism, disturbance of water balance, polyuria, polydipsia, hypothermia, headache, dizziness and fainting attacks. Dental caries has been noted by many writers and in some instances the teeth have been lost without evidence of caries.

Women appear to be more susceptible to the disease than are men in the ratio of about 5 to 1. It is most common in the fourth decade of life, though cases have been reported as early as the ninth year⁷ and as late as the sixty-ninth.⁸

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is usually not difficult unless the disease is accompanied by some other disorder giving rise to extreme cachexia. Cachexia due to tuberculosis and carcinoma is not, as a rule, accompanied by a markedly depressed metabolic rate, loss of pubic and axillary hair, loss of sexual functions and a recession of secondary sex characters. Primary hypothyroid cachexia responds readily to thyroid substitution alone.

Pluriglandular sclerosis may offer some difficulty. True cases of this rare condition show the skin and facies of myxedema and a pigmentation of the skin not found in Simmonds' disease. Pluriglandular sclerosis usually affects all the endocrine glands simultaneously and presents

features in accordance with this involvement. Some cases may offer considerable difficulty in diagnosis.

Myxedema should offer no problem in differentiation. The two conditions have little in common, with the exception of the low basal metabolic rate. Thyroid therapy produces little or no beneficial effect in Simmonds' disease.

The differential diagnosis between Simmonds' disease and Addison's disease is not always easy. Some of the clinical features of Addison's disease such as asthenia, anorexia, loss of weight, dizziness and hypotension are also features of pituitary cachexia. The pigmentation in Addison's disease should aid in the differentiation. The response to the cortical hormone in Addison's disease and the response to pituitary therapy in Simmonds' should be a valuable aid in the differential diagnosis.

Simmonds' disease should be suspected in every case of marked loss of weight in which no other cause for the emaciation can be discovered. The clinical features of the disease should enable one to make the diagnosis in nearly all cases. The response to pituitary therapy is a valuable aid in early diagnosis. The fact that many cases are due to neoplastic causes should not prevent one from giving pituitary therapy a suitable trial. In Brougher's case the condition, due to an adenoma of the pituitary, responded favorably to substitution treatment.

The following case is fairly typical of Simmonds' disease. While the diagnosis remains unverified so far as pathologic changes are concerned, the response to treatment and ultimate recovery are significantly informative.

REPORT OF CASE

A school girl, aged 17 years, had lived in Minnesota during her entire life. Her father died as a result of an accident. Her mother and one sister were living and well. There had been no family tendencies and no constitutional diatheses. She had suffered from diphtheria and whooping cough in early childhood. Her menses began at the age of 15 years and had always been irregular. At the age of 15 she began to grow very rapidly and attained her present height at that age. The development of the secondary sex characters was slow. She had little interest in the opposite sex.

The chief complaints were loss of weight, weakness, amenorrhea, somnolence, mental lethargy, falling of the hair (pubic, axillary, eyebrows, eyelashes and hair on the head), premature aging and dryness of the skin.

Five and one-half months previously the patient had stopped menstruating. Following this there was a loss of appetite and a resultant loss of weight. She noticed that her school work was becoming difficult. This was unusual, for she had always been an excellent student. The condition gradually became worse, she became weak, the skin became dry, and the pubic and axillary hair began falling out.

In June, three and one-half months following the onset of the syndrome, the condition became alarming. She was losing weight rapidly, the weakness was more marked, the somnolence and mental lethargy were becoming more prominent, falling of the hair had extended to the eyebrows, eyelashes and hair on the head, and the aging was becoming more apparent.

Fig. 2—Appearance of patient March 28 1934 weight 135 pounds (61 Kg.)

Fig. 1—Appearance of patient Aug 1 1933 weight 81 pounds (36.7 Kg.)

6 Brougher J. C. *Endocrinology* 17 130 (March April) 1933
7 Simmonds Morris *Deutsche med Wchnschr* 42 190 1916
8 Meug H. *Frankfurt Ztschr f Path* 36: 650 1928.

When I first saw the patient in August, five and one-half months following the onset, anorexia was almost complete. The ingestion of food consisted of about one-half glass of milk a day. She had spent the previous two weeks at a summer camp and had lost 14 pounds (6.4 Kg) during that time. Mental lethargy and somnolence were quite marked, the hair was falling out rapidly and the premature aging was prominent. She had lost 59 pounds (26.8 Kg) in a period of five and one-half months.

A thorough search was made for a possible psychologic factor. None could be discovered. The girl was happy in spite of her condition and was willing to cooperate in every way.

Previous treatment by several physicians had consisted of desiccated thyroid, cod liver oil, rest, sun baths and tonics.

On examination, Aug. 1, 1933, the most striking features were emaciation and an aged appearance. The girl appeared much older than 17. The hair was dry and brittle and could be pulled out easily. Her height was 5 feet 7 inches (170 cm) and her weight 87 pounds (39.5 Kg). The skin was dry but showed no abnormal pigmentation. There was no wrinkling of the face and no increase in facial lines. The eyes were sunken, the pupils reacted normally to light and in accommo-

Fig. 3—Roentgenogram of sella turcica

dation, and the visual fields were normal. The fundi appeared to be normal. The nose and throat were normal. The tonsils had been cleanly removed. The lateral incisors were small; otherwise the teeth were normal and in excellent condition. Mucous membranes were of good color and appeared to be normal. The thyroid was not palpable and there was no enlargement of the cervical glands. The breasts were atrophic. The chest showed no abnormalities. The heart dulness was within normal limits, the rate 65 per minute, rhythm was regular and no murmurs were heard. The abdominal organs could not be palpated. No abnormal masses were palpable. A vaginal examination was not made. The reflexes were normal. There was no tremor. The extremities were not edematous.

The blood pressure was 85 systolic, 60 diastolic (Tyco's recording sphygmomanometer). The urine was normal at all examinations. The red blood cell count was 4,630,000, white cell count 5,100 and hemoglobin 80 per cent. The blood Wassermann reaction was negative. The basal metabolic rate was minus 27 per cent. Fasting blood sugar was 120 mg per hundred cubic centimeters. The stool examination gave negative results.

Roentgenograms were made by Dr. Daniel M. Clark. The thoracic cage was normal. The diaphragms were smooth and there was no free fluid in the pleural cavity. The hilar shadows and bronchovascular markings had a normal appearance. The lung fields were entirely free of parenchymal pathologic changes. The mediastinum was not widened or displaced. The heart was within normal limits in size, shape and position.

Lateral studies of the sella turcica showed a pituitary fossa of normal size and contour. The clinoidal processes were well formed and there was no bridging. No evidence of a neoplastic process was seen. No adventitious calcification was noted.

The conclusion was made that there was no roentgen evidence of pathologic changes in the chest or sella turcica.

The diagnosis was Simmonds' disease (pituitary cachexia), with secondary hypo activity of the thyroid, ovaries and adrenal cortices.

The patient was given intramuscular injections of anterior pituitary-like gonadotropic principle of pregnancy urine (Fol lutein, Squibb) every other day in doses of 50 rat units. Desiccated thyroid was given by mouth in doses of one-half gram (0.03 Gm) three times a day. This treatment was continued for ten days.

The patient continued to lose weight rapidly and there was no improvement. The weight had dropped to 81 pounds (36.7 Kg). The desiccated thyroid was discontinued and the gonadotropic principle of pregnancy urine was increased to 150 rat units every other day.

Four days following the increase in dosage, the patient ate her first meal in months. In a week she had begun to gain weight and was much brighter mentally, the somnolence was much improved and she felt better in every way.

The gonadotropic principle of pregnancy urine was continued in the same dosage of 150 rat units every other day until September 18. By that time the patient had gained 10 pounds (4.5 Kg), there was no somnolence, the appetite was excellent, the hair had stopped falling out and new hair was beginning to grow. In a gain she had plenty of "pep" and the skin was normal. The aged appearance was beginning to return to that of youth.

The patient returned to her home in St. Paul and through the cooperation of Dr. M. A. Shillington the gonadotropic principle of pregnancy urine was continued. The dosage, however, was decreased to 75 rat units and the intervals between injections were gradually lengthened. The last administration of the gonadotropic substance was given on December 14. During this time she had continued to improve and her condition, Jan. 1, 1934, was believed to be normal. She entered the University of Minnesota shortly after this and maintained an A average at that institution during the following quarter.

The patient received approximately 5,000 rat units of gonadotropic principle of pregnancy urine in a period of four and one-half months.

On examination, March 28, the weight was 133 pounds (60.3 Kg), a total gain of 52 pounds (23.6 Kg). The height was 5 feet 8 inches (173 cm), an increase of 1 inch (2.5 cm). The skin appeared to be normal, the cheeks were rosy, and the hair was growing rapidly and was thicker than at any time previous to the onset of the syndrome. There was a marked improvement in the secondary sex characters, the breasts were larger, the pubic hair was much more abundant, and the labia had increased in size. The blood pressure was 110 systolic and 85 diastolic. The basal metabolic rate was plus 4 per cent. No abnormalities could be found, and the girl appeared normal in every way. She stated that she could not remember ever feeling as well and that she had more energy and vitality than she had had in years. There had been a definite turn in the feeling toward the opposite sex.

On reexamination, November 30, the weight was 129 pounds (58.5 Kg) and the height 5 feet 8 inches. No abnormalities could be found, and the patient stated that she never felt better than she did at present. August 24, she had her first menstruation since the onset of the illness. The period was normal and lasted four days. Three subsequent menstrual periods were regular and normal.

During the past few years, several cases have been reported in which substitution therapy has given striking results. Among these are the cases of Calder,⁹ Striker,¹⁰ Constantini,¹¹ Hürthle,¹² McGovern¹³ and

13 McGovern B. E. Endocrinology 16:402 (July-Aug.) 1933.

Brougher⁶ In most of these cases, an extract of the whole anterior pituitary gland was used

In the case here reported, a sterile glycerin solution of anterior pituitary-like gonadotropic principle of pregnancy urine was used. As to whether the substance is of placental or hypophyseal origin has not been definitely determined. It is difficult to explain the action of the anterior pituitary-like gonadotropic substance in this case. The observations, however, would lead one to believe that it is certainly more than an activator of the sex hormone, and there is a possibility that it produces a definite stimulation of the hormone activity of the entire anterior lobe of the pituitary gland.

An anterior pituitary extract was available for use when the girl was first seen. The extract contains the growth factor together with the sex and thyrotropic complementary factors of the hypophysis. A marked increase in height within a few months was obtained in two cases in which the patient had been previously treated with this extract. The girl had already attained the height of 5 feet 7 inches at the age of 17 years, and it is obvious that the use of the extract containing the growth factor would have been objectionable in this case.

Desiccated thyroid was given in small doses in the early treatment of the patient. It is thought by some investigators that better results may be obtained in pituitary disorders when desiccated thyroid is given with pituitary therapy, especially when the basal metabolic rate is low. The results with thyroid therapy alone in the treatment of Simmonds' disease have been without beneficial effect.

When one considers the etiology of Simmonds' disease one must remember that it may be caused by transitory functional disorder of the anterior lobe. Among conditions causing such disorders may be focal infections, constitutional factors and functional exhaustion of the cells of the anterior lobe of the pituitary body. It is possible that mild cases of Simmonds' disease of this type are common and are unrecognized. Von Bergmann¹⁴ considers the most important and most frequent form of emaciation a condition that has been referred to as "hypophyseal emaciation." He is convinced that the anterior lobe of the pituitary body is an important factor in this form of emaciation and considers the extracts of the anterior lobe the most effective therapy. The condition of "hypophyseal emaciation" is similar in many respects to Simmonds' disease, and it is possible that it is a mild form of Simmonds' disease.

The etiologic factor in the case here reported was probably a functional disorder of the anterior lobe. This is suggested by the normal appearance of the sella turcica and the response to therapy.

SUMMARY

Simmonds' disease is probably more common than is generally realized.

The syndrome may be caused by transitory functional disorder of the anterior pituitary body as well as by neoplastic involvement.

In a girl, aged 17 years suffering from Simmonds' disease, the treatment consisted of injections of anterior pituitary-like gonadotropic principle of pregnancy urine for four and one-half months and small doses of desiccated thyroid for a short time. Improvement followed the increase in dosage of the gonadotropic substance.

The clinical features of the syndrome, together with more recent knowledge of the anterior hypophysis, indicate that the entire anterior hypophysis is involved in Simmonds' disease. It is possible that the hormone activity of the entire anterior lobe of the hypophysis is stimulated by gonadotropic substance.

Clinical Notes, Suggestions and New Instruments

A GONGYLONEMA INFESTATION IN MAN

C H WAITE, B A AND RACHAEL GORRIE, M S, MOBILE, ALA

Gongylonema has been found in man in such rare instances that we believe that the circumstances of the isolation and identification, as well as a description, of one found by us may be of interest.

The infestation is common in ruminants, swine and other animals,¹ in which it is found in the upper portion of the digestive tract, and usually in the esophagus. Only seven cases have been found in man, the most recent by Stiles² in 1928. Pane has found one, Alessandrini one,³ Ward one,⁴ Stiles three, and Ransom one. In all human cases the worm has been found in the oral cavity, where it burrows beneath the mucosa. The patient is conscious of its migrations and it can be seen with the naked eye.

Anterior (above) and posterior (below) extremities of Gongylonema (X 75)

L. H., a white man, aged 30, brought a worm to our laboratory stating that he had withdrawn it with his fingers from the "roof of his mouth." He had suffered with a sore mouth for three months. Although the man occasionally felt an indefinite movement when the worm burrowed beneath the oral mucosa, no specific symptoms developed, and he stated that the only effect he felt was nervousness. Faust states that in one case an antiseptic mouth wash stimulated the worm to work its way out of its tunnel so that it was removed with the fingers. It is quite possible that this was true in our case, as treatment for Vincent's angina had been employed for several weeks before extraction of the worm. An examination of the man's palate was not made at the time the worm was extracted, but one week later no evidence of the tunnels or paths caused by the worm beneath the mucous surface could be seen.

From the Alabama State Board of Health Branch Laboratory
1. Faust, E. C. Human Helminthology Philadelphia Lea & Febiger 1929

2. Stiles C. W. and Baker C. E. A Fifth Case of Gongylonema Hominis in Man in the United States J. A. M. A. 91: 1891 (Dec 15) 1928. Stiles, C. W. Gongylonema Hominis in Man, Pub. Health Rep. 36: 1177 (May 27) 1921. Annual Report of the Surgeon General of the Public Health Service for 1918 p. 64.

3. Alessandrini G. Nuovo caso di parassitismo nell'uomo da Gongylonema Bull. d. r. acad. med. di Roma 40: number 4 1914.
4. Ward H. B. Gongylonema in the Role of a Human Parasite J. Parasitol. 2: 119-125 (March) 1916.

The worm is, we believe, the first male *Gongylonema* found in man and was described as follows. It was a grayish white, 32 mm long by 0.1 mm. in width, with the posterior extremity slightly curved. The mouth was small and circular, surrounded by a raised cuticular rim 15 microns in diameter. From the mouth caudad the body was embossed with eight longitudinal rows of cuticular scutes extending for 0.47 mm. These bosses or scutes are the characteristic feature of the *Gongylonema*. They are quite regular in succession and uniform in size.

The posterior end showed distinct caudal alae supported by ten pairs of pedunculated papillae. The copulatory spicules were unequal in length, one measuring 50 microns, while the other was 16.5 mm. The gubernaculum was discernible. The anus was 0.14 mm anterior to the caudal tip.

Gongylonemas isolated from man, swine and cattle are very similar, but the species have been given a variety of names by various investigators. Until definite dissimilar structures in the species are established, we are inclined to think, as do Faust and Ward, that the most appropriate name for the nematode would be *Gongylonema pulchrum* (Molin, 1857).

It is now some six weeks since L. H. brought the worm to us. His nervous symptoms are gone, his palate is normal and he has found no more worms. In all but one of the previous cases, only one worm has been found, from this evidence it seems safe to assume that the infestation in man is accidental.¹

Thursday he was a little confused and complained of a headache but was otherwise normal. He had no double vision.

Friday, the sixth day from the very first manifestation of illness and the fifth from the severe onset, found him well but for weakness and a slight headache when sitting upright. Since then he has remained perfectly well in every way.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

THERAPEUTICS OF THE THYROID

J. H. MEANS, M.D.
BOSTON

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed, the series will be published in book form.—Ed

One dictionary defines therapeutics as "the practical branch of medicine dealing with the treatment of disease." In this article "therapeutics" is interpreted to include both treatment of diseases of the thyroid and treatment of any diseases by means of the gland. The treatment of hypothyroidism, for example, is substitution therapy with thyroid, but there are also certain nonthyroid disorders in which thyroid may be used as a drug for the sake of its pharmacodynamic action, just as epinephrine is used in asthma. The latter is symptomatic, not specific substitution therapy. It is treatment with a gland secretion, not treatment of a gland disease. Both will be discussed in this article.

TREATMENT OF THYROID DISEASES

The treatment of thyroid diseases or disorders resolves itself chiefly into that of excessive function of the gland, insufficient function of the gland, and local mischief caused by the gland.

In identifying methods to meet these several indications it will be well to think always in terms of known thyroid physiology, or in those of the anatomic relations of that organ.

The sole function of the thyroid, so far as is known, is the manufacture of the hormone thyroxine, but the physiologic actions of the substance are varied and have to do with metabolism, homeostasis, irritability, differentiation and growth.

For the purpose of discussion it will be convenient to consider the clinical pictures, associated with the thyroid, under the following headings:

- 1 Thyrotoxicosis—toxic goiter
- 2 Myxedema and cretinism.
- 3 Endemic goiter, sporadic colloid goiter
- 4 Nodular goiter
- 5 Malignant goiter
- 6 Inflammation of the thyroid
- 7 Anomalies of the thyroid

Of these several groups, the first two include lesions producing gross alteration in thyroid function and, therefore, constitutional manifestations both characteristic and important. The remainder include lesions for the most part of local significance. By the term "goiter" is meant enlargement of the thyroid from any cause. It is used in a purely clinical sense and has no pathologic connotation. This is consistent with common use in this country today and is justified by the fact that the

ENCEPHALITIS COMPLICATING GERMAN MEASLES

REPORT OF CASE

H. O. SKINNER, M.D., ST. PAUL

A boy, aged almost 10 years, of good physique, nutrition and general health, was sent home from school on Wednesday, Feb. 6, 1935, with the diagnosis of German measles and the information that a physician was not needed for this disease. He did not seem very sick and his rash was about gone by Friday night.

Saturday he was irritable, ate very little and slept much of the day. Sunday he awakened apparently well, had a rising bed-tussle with his 5 year old brother, made several trips downstairs and read the "funnies." About 9 o'clock in the morning, while talking with his mother, he fell unconscious to the floor. Arriving soon afterward I found him absolutely unconscious, with pupils widely dilated, equal and without reflex. Superficial reflexes were gone, the patellar was faint, and the Babinski sign was positive. The eardrums were normal in appearance. He was restless but not convulsive, and resistive but not rigid, except for his jaw. His neck particularly was not rigid and he had no meningeal symptoms. He had had involuntary evacuation of bowels and bladder but his pulse was only 72 and the temperature (rectal) 98.6 F.

He was given morphine by hypodermic at once and again that night, at which time he was still very restless, with no change in his other symptoms.

Monday morning the pupils were sluggishly reactive to light, and the Babinski sign was doubtful. Lumbar puncture gave 1 ounce of fluid under moderate pressure, it was clear, the Nonne reaction was negative, and it contained 13 cells. Urinalysis at this time showed specific gravity, 1.018, the urine was clear and acid, and negative for albumin and sugar. Microscopic examination was negative. A neurologic consultant confirmed my diagnosis of encephalitis but said that he had seen a few cases of encephalitis complicating German measles which were distinguished from the lethargic type by their very short and mild course.

The boy was given an enema of magnesium sulphate followed by retention enemas of dextrose in saline solution. On the evening of the second day of unconsciousness he ran a little fever.

Tuesday his temperature reached 103 F., but it was normal by the next morning and remained so. He was still sufficiently restless for morphine and unconscious but he did respond irritably to being moved. His rigid jaw relaxed, he yawned several times and was able to swallow.

Wednesday he looked about, asked for food but didn't eat it. Restlessness lessened and the pulse, temperature and reflexes were normal.

pathologic nature of an enlargement often cannot be identified clinically "The patient has a goiter, it is (or isn't) accompanied by hyper- (or hypo-) function," is sometimes all the physician can say with certainty as the result of his purely clinical studies. By the term "thyrotoxicosis" is meant the toxic state resulting from an excessive supply of thyroxine. It can be induced by the administration of thyroid or thyroxine but exists spontaneously only in conjunction with thyroid hyperplasia, hence the term toxic goiter. From the therapeutic side, nothing is gained by trying to split toxic goiter into two or more types. The treatment for all is the same.

1 Toxic Goiter—The indication is to abolish the hyperfunctioning of the gland. To date only two procedures are known that can accomplish this permanently: irradiation and surgical resection of the thyroid. It is to be borne in mind that the disease may subside or even disappear spontaneously in time. Also, it should be stated emphatically that iodine characteristically produces a marked amelioration in the intensity of the thyrotoxicosis, which, however, returns to its former state if the administration of iodine is stopped.

The response to iodine has come to be looked on as one of the cardinal manifestations of the disease.¹ Advantage can be taken of it not only in treatment but in diagnosis,² and probably in prognosis as well. It consists in a prompt fall in metabolic and pulse rates and improvement in the symptoms of thyrotoxicosis. It can be obtained at any time during the course of the disease but has no effect on the duration or direction of its progress. If a patient is kept continually under the influence of iodine, the course will be milder but not shorter than of one who is not. We³ believe that there is no true refractoriness to iodine. The only people who do not respond to iodine are those who are either not thyrotoxic or those who, if thyrotoxic, are already iodimized. In but 3 per cent of our cases was there a failure to respond to iodine, and these could be explained on the basis that the drug was given at a time when the disease was increasing rapidly in severity and the iodine effect was merely to hold the status constant. In the management of toxic goiter, the physician must know whether his patient is iodimized or not iodimized, just as he must know whether his cardiac patient is digitalized or not digitalized. An adequate dose of iodine,⁴ to attain full iodimization in toxic goiter, is contained in from 5 to 10 minims (0.3 to 0.6 cc) of saturated solution of potassium or sodium iodide, given once daily. There is no special virtue in compound solution of iodine or other iodine preparations. Iodine seems to serve as iodine, regardless of chemical combination or route of entry. It may be administered by mouth, vein or rectum and is equally effective by all routes.⁵

Irradiation in some cases seems to put a permanent quietus on the hyperfunctioning of the thyroid. It may be given in the form of radium or roentgen radiation. Before 1923 (the date Plummer introduced the use of

iodine), Holmes and I⁶ recommended treatment with roentgen radiation in all cases. We found that in about one third it brought about a cure, in another third it produced improvement, and in another third it was without observable effect. We have lately looked up a number of patients treated ten or more years ago. It is of interest that, for the most part, the cures have proved permanent.⁷

Operations less extensive than subtotal thyroidectomy, in our experience, have generally proved inadequate to bring about either a complete or a lasting cure.⁸ It is true that patients in the past who have had hemithyroidectomies may be entirely well after several years. This is because the surgical procedure improves the condition, and in time nature completes the cure. The thyrotoxicosis is not promptly and completely abolished, as it is in most cases in which subtotal thyroidectomy is done.

At the present time I believe that the best therapeutic program available is subtotal thyroidectomy in the fully iodimized subject. This program offers more promise of certain and prompt recovery than any other that I know. Irradiation, though sometimes effective, is unquestionably inferior. One of the strongest arguments for it in the past was that surgery was dangerous. The preoperative use of iodine has greatly diminished the risk of operation. The disease itself sometimes kills the unoperated patient. We have had six such deaths in ten years, a mortality of about 0.6 per cent.

Our routine procedure in toxic goiter is to put the patient to bed, observe the symptoms carefully and determine the basal metabolic rate every day or two until a horizontal level has been obtained. Iodine is then given for from ten to fourteen days and the effect on the symptoms and metabolic rate is noted. If a definite response to iodine is obtained, which means a drop of from fifteen to thirty points in the metabolic rate and improvement in symptoms, the patient is ready for operation. The operation is, if possible, a one stage subtotal thyroidectomy under nitrous oxide-oxygen or local anesthesia.

Patients who have not made a good response to iodine and patients who have been emotionally upset prior to operation are poor operative risks. They are more subject to postoperative toxic crisis or storm. Older persons are less good risks than young and those with cardiac complications less good than those without. In all cases, steps should be carried out preoperatively to insure a good store of glycogen in the liver. In the very toxic ones, intravenous dextrose should be given the day before and on the morning of the operation (a liter of 5 per cent), in others a high carbohydrate diet, with sugar candy, will serve. Sedation is accomplished by bromides, paraldehyde, morphine or amytal. Phenobarbital is undesirable, because thyrotoxic persons seem particularly subject to severe rashes.

Patients with gross congestive heart failure or permanent auricular fibrillation should be digitalized as well as iodimized before operation. When the metabolic rate is rising in spite of iodine, operation should be deferred. Active streptococcal throat infections or other active infections, including particularly respira-

tory involvement and active rheumatic infection, are also indications for postponement⁹

Following operation, dextrose is again given intravenously to the patients who seem very toxic, or it may be given rectally and in conjunction with bromides. Iodine is continued until the patient is discharged from the hospital. During the immediate postoperative convalescence, inhalations of steam, flavored by compound tincture of benzoin, are very soothing to the irritated trachea. These should be given by means of a 3 foot piece of 1 inch rubber tubing, connected to the spout of a kettle containing the hot water and benzoin, which the patient places in his mouth and breathes through¹⁰. The water in the kettle, obviously, must not cover the inner opening of the spout. Paper cones and bags are unsatisfactory. Postoperative hypoparathyroidism (tetany) is treated by means of intravenous calcium chloride, in the dose of 5 cc of 10 per cent solution, and calcium lactate or gluconate by mouth, 30 grains (2 Gm) three times a day, laryngeal obstruction by means of intubation or tracheotomy, if necessary, and postoperative toxic crisis by intravenous dextrose, an oxygen tent, sedatives and cold sponging or packs.

Following discharge from the hospital, the patient is followed at gradually lengthening intervals for at least two years. This is for the purpose of detecting recurrent thyrotoxicosis, or myxedema or latent tetany.

Often mild symptoms of thyrotoxicosis persist for a few months after operation. These may be entirely controlled by small rations of iodine (potassium iodide 3 grains [0.2 Gm] once daily or less). The indication is to omit the ration from time to time, and when no rise in basal metabolic rate or no return of symptoms occurs, the patient may be considered cured. More serious persistence or recurrence of thyrotoxicosis requires more drastic treatment. Irradiation may be tried or, if marked regrowth of goiter occurs, a second or even a third operation may be necessary.

Such a program at the Massachusetts General Hospital has given, in round numbers, the following results. Four out of five patients are cured. One out of five has persistent thyrotoxicosis. One out of ten requires further operation or irradiation. One out of 100 develops permanent myxedema requiring continued substitution therapy with thyroid¹¹. Over a ten year period, the operative mortality in the public wards has been 1.1 per cent in the 97 per cent of the patients making good iodine responses, and 27.3 per cent in the 3 per cent not responding well to iodine. It was this finding that led us to conclude that a poor response to iodine is indication of poor operative risk.

The keeping of operative mortality down is more a matter of wise selection of patients and time of operation, and of preoperative and postoperative care, than it is of improving surgical skill. The operation itself is highly standardized and, in the hands of a properly qualified surgeon, easy and safe. There are unquestionably more good thyroid surgeons in the United States than in any other country, and the surgical technic here is more nearly perfected.

The experience at the Massachusetts General Hospital justifies the following conclusions. 1. If, after

subtotal thyroidectomy, the basal metabolic rate drops to and remains within standard limits, off iodine, for two months, cure can be assured. 2. A standard basal metabolic rate, on iodine, two weeks after operation does not mean that cure can be assured. 3. A basal metabolic rate of plus 15, or higher, on iodine, two weeks after operation, usually means that the disease has not been effectively abolished¹².

Of other therapeutic procedures in the management of toxic goiter, little need be said. Quinine hydrobromide has no longer any place. Quinidine may be used for fibrillation persisting after operation. Cytolytic serums and antihormonal substances have not yet impressed the profession sufficiently with their usefulness to lead to general adoption.

2. Myxedema and Cretinism.—In these states one is dealing with a loss of thyroid function. In adult myxedema the indication is to give a sufficient daily ration of thyroid to keep the patient free from symptoms. It is best to use the minimum dose that will accomplish this purpose. Nothing is gained by raising the basal metabolic rate to standard if the patient is free from symptoms (as is usually the case) at a decidedly lower level. In our experience, patients seldom have symptoms of myxedema when the basal metabolic rate is above minus 20¹³. From 1 to 2 grains (0.06 to 0.12 Gm) of thyroid U. S. P. once daily by mouth is often sufficient. Many patients will remain nearly symptom free on less. In the cases of thyroidectomized cardiac patients, in whom the indication is to get the maximum metabolic reduction possible without gross myxedema, rations as low as one-fourth or even one-eighth grain (0.016 or 0.008 Gm) may serve. Since a sensation of warmth is desirable in winter and undesirable in summer, it may be well to give a somewhat larger ration of thyroid in winter than in summer. In the dog days it is a positive advantage, to be, to a certain extent, myxedematous.

Since the strengths of commercial thyroid preparations differ, one from another, it is desirable that the physician stick to one brand and learn its effective dose. The U. S. Pharmacopeia X requirements are as follows:

Thyroid is the cleaned, dried, and powdered thyroid gland, previously deprived of connective tissue and fat. Thyroid contains not less than 0.17 and not more than 0.23 per cent of iodine in thyroid combination, and must be free from iodine in inorganic or any other form of combination than that peculiar to the thyroid gland. One part corresponds to approximately 5 parts of fresh gland.

It is worth noting that it is not an extract, though commonly so miscalled. Not all commercial brands conform to this pharmacopeial requirement, which is a pity because it makes for confusion. Armour's, Lederle's and Lilly's do, Parke, Davis's and Burroughs, Wellcome's do not. The latter, of course, is a British preparation. In our experience, the following are all equal in calorigenic effect in myxedema patients: 1½ grains (0.1 Gm) of U. S. P. (Armour, Lederle or Lilly) thyroid, 1 grain (0.065 Gm) of Parke, Davis thyroid, 5 grains (0.3 Gm) of Burroughs, Wellcome thyroid, or 0.3 mg of pure thyroxine¹³.

It should be borne in mind that as a therapeutic agent pure thyroxine has no advantage over dried thyroid, indeed, by mouth it is inferior, for in the whole gland

the hormone is in protein linkage as iodothyroglobulin, it is more soluble, and is absorbed from the gastrointestinal tract in a quantitative manner¹⁴. Nor have other fancy and more expensive thyroid pharmaceuticals anything to recommend them. Dried thyroid by mouth is practically a perfect substitution therapy. It is the only one that need be employed in the treatment of myxedema.

The effects of giving thyroid in myxedema are prompt and striking. In a few days the patient feels warmer and less sleepy. His speech and muscular movements become faster. His sensorium becomes more alert. There is usually a striking diuresis. As fluid goes out, the bloated appearance disappears. With faster skin growth there is desquamation. Indeed, sometimes these people practically shed their skin. The hair takes on a more normal texture and grows faster. In a fortnight the status may be close to normal. The rapid disappearance of symptoms is in contrast to their slow development.

If excessive dosage is given there may be untoward manifestations. Sometimes these take the form of marked aching and even tenderness in skeletal muscles. Sometimes attacks of angina pectoris are produced. Coronaries that were adequate at the low level of myxedema become inadequate when metabolism is suddenly increased. Acute cardiac collapse, from overdosage, has been reported.¹⁵

For these reasons the physician will do well to go slowly in inaugurating substitution therapy. Indeed, there is no need to do more than start what is to be the probable permanent ration. As previously stated, this is in the neighborhood of 1 to 2 grains (0.06 to 0.12 Gm.) of U S P thyroid, once daily. If untoward symptoms arise (they seldom will on this dosage), thyroid should be stopped till they disappear, then should be resumed in smaller dosage.

Certain by-products of myxedema need mention. The anemia is often impressive. Usually it is of the so-called secondary variety,¹⁶ occasionally the picture is that of pernicious anemia.¹⁷ When the former is the case, iron in full dosage (that is, iron and ammonium citrate 30 grains, or 2 Gm., three times a day) in addition to thyroid may effect a faster restoration of blood than thyroid alone, and when the latter, liver or a potent liver extract should be given along with thyroid. Anemia is the slowest myxedema symptom to disappear under treatment with thyroid alone.

The heart in myxedema is enlarged and flabby, in fact, myxedematous, but thyroid is all the medication that is required.¹⁸ Digitalis contributes nothing, indeed is not indicated, unless some independent heart disease with congestive failure coexists.

A warning is in order regarding morphine. The tolerance to this drug is greatly lowered.¹⁹ A single quarter grain dose may put the myxedema patient into a deep lethargy, which conceivably could be fatal. The drug should not be used in the untreated patient.

In the cretin, the principles of treatment are similar to those in adult myxedema, except that sufficient

thyroid must be given to permit a normal rate of growth. The adult with acquired myxedema has been a normal person and by adequate substitution therapy can be restored to that happy status. The cretin, on the other hand, has been athyrotic since birth and, unless adequate substitution therapy is started in the first year or two of life, an irreparable stunting in mental and bodily growth will occur, which no amount of later treatment can correct. The effect of thyroid in the older cretinous imbecile is often disappointing. Sometimes it seems to make him rather irritable and peevish and little else. Suitable dosage for cretins, of U S P thyroid, is approximately as given in the accompanying table.

Suitable Dosage of Thyroid for Cretins

Age	Amount Daily
2-4 months	$\frac{1}{10}$ grain
4-8 months	$\frac{2}{10}$ grain
8-12 months	$\frac{2}{10}$ to $\frac{3}{10}$ grain
12-24 months	$\frac{3}{10}$ to $\frac{1}{2}$ grain
2-4 years	$\frac{1}{2}$ to 1 grain
4-12 years	1 to 2 grains

Acquired myxedema, supervening in childhood, occupies an intermediate position. Treatment here can give nearly as good results as in the adult, if faithfully adhered to.

3 Endemic Goiter and Sporadic Colloid Goiter—In endemic goiter the important thing is prevention, not treatment. This is discussed in the paper by Marine.

Treatment of the endemic goiter or the sporadic colloid goiter is indicated when it produces pressure or becomes the seat of pathologic changes, or for cosmetic reasons. Iodine accomplishes but little after goiter has developed. Thyroid should be given if the metabolism is low. For the most part, the treatment is surgical removal or nothing.

4 Nodular Goiter—This term is purely one of convenience. Any goiter with lumps in it can be called nodular. Only the pathologist can say with certainty what the lumps may be. Such goiters, however, constitute a fairly definite clinical grouping. Treatment is indicated for pressure, which is frequent, or for thyrotoxicosis, or for the possibility or prevention of a malignant condition or for cosmetic reasons. There is no medical treatment for nodular goiter. If the symptoms of pressure are present, operative removal should always be advised. If a state of thyrotoxicosis supervenes, the treatment is that of toxic goiter, which has already been described. Some authorities advise removal of all nodular goiters, on the ground of cancer prophylaxis. There is no question that malignant disease develops more frequently in nodular goiter than in the normal thyroid. To this extent nodular goiter may be looked on as a premalignant lesion. If one takes a somewhat more conservative attitude toward treatment, one must still advise surgical resection if growth or change in consistency of the goiter develops. Anything short of that would be negligent. The long standing, unchanging, asymptomatic, nodular goiter offers the chief opportunity for argument.

5 Malignant Goiter—An inoperable thyroid cancer is a horrible lesion. It is one's duty to prevent such a development at all possible cost. Early detection and eradication in an operable stage is the obvious course.

All degrees of malignancy are encountered from very slowly progressing forms to truly fulminating types.²⁰

The latter are practically never cured. The former often are. So long as the disease remains within the gland capsule, there is hope of successful ablation. Even when there is slight extension beyond the capsule there is still some possibility of complete removal by sacrificing the overlying muscles and other nonessential adnexa.

Surgical treatment for malignant goiter should be followed by irradiation, and inoperable growths may be treated by this method alone. Thyroid malignancy often responds well to irradiation, particularly when it is lymphosarcomatous instead of carcinomatous. Primary tumors respond better than metastases. Irradiation should not replace surgery even when only partial resection is possible. Papillary adenocarcinoma is especially amenable to treatment in these ways.

6 Inflammation of the Thyroid—Acute thyroiditis turns up now and then, either in persons with goiter or in those with normal thyroids. The indications for treatment are those of any infection: rest in bed, and so forth, together with an ice collar locally. Under this regimen most cases subside rapidly and clear up completely. Occasionally the process goes to suppuration and then there is danger of suffocation from pressure or inward pointing with rupture into the trachea or mediastinum. If suppuration is suspected an exploratory puncture may find the pus, and then anterior drainage should be done.

Chronic thyroiditis appears in several forms, of importance chiefly because they may be productive of pressure or of myxedema. The former may be relieved by operation, the latter by giving thyroid. Such glands may be intensely hard and may closely resemble a malignant growth.

7 Anomalies of the Thyroid—Aberrant thyroid tissue may be found at the back of the tongue, along the course of the thyroglossal duct, in the neck lateral to the usual thyroid, or in the mediastinum. In any of these positions, surgical removal may be indicated if any mischief is being done or is impending, i.e., pressure, malignancy or hyperfunction. Lateral aberrant thyroids are particularly likely to become the seat of papillary cyst adenoma and should always be removed for prophylaxis.

The thyroglossal duct may persist and give rise to a thyroglossal cyst. These may become infected and rupture spontaneously or require drainage. When this happens, a sinus is found that can be eradicated only by complete dissection of the cyst.

THE USE OF THE THYROID HORMONE AS A DRUG

In contrast to its use in myxedema, in which it is a direct substitute for a hormone that the body needs and cannot make for itself, thyroid may be tried in a variety of nonthyroid disorders for the sake of its drug action. The action wanted may be the calorogenic, the diuretic, the diaphoretic, the effect on other endocrines such as the female gonads, the direct effect on heart muscle, the stimulation of the vegetative nervous system with, for example, increased peristalsis and relief of constipation, or any other that it possesses.

The physician, in using the drug, should think of all its actions and give it when he would like to obtain, in his patients, such effects as it may conceivably produce. He should also remember that dried thyroid, U S P, is the form of choice, not pure thyroxine or any special pharmaceutical.

1 Hypometabolism Without Myxedema—A considerable number of persons turn up with basal metabolic rates well below standard who show no clinical evidence of thyroid disease and in all probability have no thyroid disease. The low metabolic rate is brought about in some other fashion than through lack of thyroxine. Some of these are, as far as can be discovered, perfectly healthy persons. When symptoms occur under such circumstances, they are of varied sorts. Sometimes the picture is that of mental depression, sometimes malnutrition. Or the picture may be that of arthritis, it may be Meniere's disease, it may be recurring corneal ulcer, it may be vasomotor rhinitis or some other anaphylactic manifestation, it may be constipation, or it may be any sort of neurasthenia. Given any of these pictures in association with a low metabolic rate, the empirical use of thyroid is justified. If it confers any benefit (it may or it may not), the physician and patient may both be thankful. If it does not, it should be discontinued. The reaction of the true hypothyroid individual is definite, precise and predictable, that of these nonmyxedematous patients with low metabolic rate indefinite, variable and unpredictable. One is biologic substitution therapy, the other drug therapy. Even for its drug action, it is seldom wise to give more than 3 grains (0.2 Gm.) of U S P thyroid daily, for any great length of time.

2 Obesity—Thyroid, of course, has been used for reduction purposes for years. It will reduce, but it is by producing hyperthyroidism that it does so. Symptoms of tachycardia, perhaps precordial pain, nervousness, irritability, warmth and sweating are apt to result. I have always been rather opposed to its use for such a purpose, except in the face of very special indications. However, I am bound to confess that I believe it less risky to use thyroid and produce a mild hyperthyroidism that will subside when the drug is stopped than to employ alpha-dinitrophenol or (4,6) dinitroorthocresol, now so much in vogue, of which the possible toxic effects, by no means fully known, are serious.²¹

3 Pregnancy and Sterility—Pregnant women with nontoxic goiters and slightly low metabolic rates had best be given thyroid during pregnancy. Certain sterile or habitually aborting women may become fertile and go through normal pregnancies if placed on thyroid.

4 Skin Diseases—Certain skin lesions characterized by dryness, particularly senile eczemas, ichthyosis and scleroderma, sometimes are improved by thyroid. The benefit here probably depends on the increased moisture of the skin induced by thyroid and perhaps by acceleration of skin growth.

5 Heart Block—Thyroid has been advocated as a preventive of Stokes-Adams attacks. According to Dr. P. D. White, its action in such cases depends on direct excitation of the ventricles.

6 Nephrosis—Epstein²² originally advocated thyroid in the type of nephropathy described by him. Its effect was largely diuretic. I have tried it in such cases but without brilliant results.

Other conditions in which thyroid might be helpful, by virtue of some one or more of its many actions, may present themselves, but those mentioned, in my experience, are the most important.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, MD
CHICAGO

NOTE.—In their elaboration these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—Ed

THERAPY OF PUERPERAL SEPSIS

OUTLINE BY DR. A. F. LASH

In this infection of the uterus and its surrounding structures occurring after the termination of a pregnancy, the available resources of prevention are a great deal better than the means of cure.

PROPHYLAXIS

Antepartum Care—All foci of infection in the tonsils, sinuses, cervix and external genitalia should be eliminated. By means of proper diet and good personal hygiene, one should aim to bring the expectant mother to the onset of labor in a fine physical condition with maximum resistance against the unavoidable infection, for, no matter what precautions are taken—what antiseptics are used—the vagina of every woman in labor contains micro-organisms that will have invaded the puerperal uterine cavity by the third day.

Obstetric Care—The problem is twofold: to exclude all organisms that might be pathogenic to the individual and to avoid all conditions that lower resistance.

Elimination of Exogenous Infection 1 Hemolytic streptococcus carriers must be resolutely excluded from contact with women during labor and the puerperium, for the carrier is a great menace. This includes avoidance of general visiting. This means that cultures must be taken as a routine from the noses and throats of the entire obstetric personnel: nurses, physicians and students. Individuals having positive cultures must be barred until, by appropriate treatment, two successive negative cultures have been secured. A physician, nurse or student having recently attended a case of contagious disease should not be permitted to come near an obstetric patient. Patients who are streptococcus carriers in their genital tract, even though they are free from symptoms, should be isolated from other puerperas quite as carefully as those who are actually suffering from puerperal infection, and the personnel caring for such patients should not be permitted to take care of "clean" cases.

2 Four thicknesses of gauze should cover the nose and mouth of every person who comes in contact with a woman during labor or the puerperium. This means that the mask must be worn not only during the delivery but by any one, nurse or physician, who removes the perineal dressings in the wards.

3 Vaginal examinations should be as few as possible and should be made with precautions of asepsis not only as to the wearing of mask and gloves and the sponging of the area surrounding the vaginal orifice with anti-

septic solution (2 per cent dilution of Compound Solution of Cresol) but also with full exposure of the vulva, complete separation of the labia, and direct introduction of the sterile examining finger without contact with the external parts.

4 Surgical asepsis must be observed during parturition. The details are too intricate to permit exposition here, and too well known to require it.

Prevention of the Lowering of Resistance—This is brought about by averting exhaustion during labor, avoiding all unnecessary trauma, and preventing excessive loss of blood.

1 Averting exhaustion includes consideration being given to diet, rest and sleep, the care of the bladder and bowels, and the prevention of excessively prolonged labor.

The diet should be high in carbohydrate and easily digestible, semisolid food being employed for the first day or two of the puerperium, after which the patient is placed on a full ward diet.

Rest and sleep are favored by the employment of obstetric analgesia. (a) Morphine sulphate (from 10 to 15 mg.) hypodermically may be used to give the patient a resting period of from two to four hours in a prolonged labor, and this injection may even be repeated once if a second rest period should be considered necessary, provided it is not employed within two or three hours of the termination of the labor to avoid the birth of a narcotized infant. Hence it should ordinarily not be given after the cervix is two thirds dilated in a primipara or one third dilated in a multipara. (b) Chloral hydrate (from 1.3 to 2 Gm.) may be given in starch water (120 cc.) by rectum as a synergist to the morphine, especially because it favors relaxation and dilatation of the cervix. (c) Inhalation anesthesia is preferred for the termination of the second stage. While ethylene and oxygen might be the method of choice, its expensiveness and the danger of explosion render the use of nitrous oxide and oxygen desirable, supplemented, if necessary, by small amounts of ether for terminal anesthesia. Prolonged and deep anesthesia should not be employed, for it delays labor, inviting operative intervention, and it favors postpartum hemorrhage, which lessens resistance.

Care of the Bladder The patient should be encouraged to urinate at least every two hours during labor. If she is unable to do so and distention of the bladder makes its appearance suprapubically, aseptic catheterization is required, by means of a soft rubber male catheter of about No. 10 size (English). If there is difficulty in getting the catheter into the bladder, the presenting part may possibly be pushed back by means of two fingers along the urethra. A distended bladder may cause "uterine inertia," and its evacuation will allow labor to proceed. During the puerperium there is a considerable tendency to overdistention of the bladder, which must be prevented by aseptic catheterization every eight hours until the patient is able to urinate voluntarily.

Care of the Bowels The rectum should be emptied by means of a soap suds (1 liter) enema as soon as labor actually sets in. In the second stage, and in multiparas even late in the first stage, enemas and cathartics are contraindicated. During the recovery from labor, cathartics should not be employed as a routine but only when definitely indicated and not earlier than on the third day after labor. Laxative food, which may be

started quite early after delivery, and Liquid Petrolatum or its Emulsion may suffice. If not, an enema may be resorted to. Saline laxatives and evacuants that produce liquid diarrheal stools should be avoided at all times.

2 Avoidance of unnecessary trauma requires the application of a high degree of obstetric judgment and skill. Patience and gentleness will go far toward preventing lacerations and bruises. Operative procedures should be reduced to a minimum and be carried out only under proper conditions. While low forceps delivery expertly done when indicated does not increase the incidence of infection, high forceps and mid forceps deliveries do. Hence these procedures should not be resorted to unless absolutely demanded, but when indicated they should not be postponed, as the earlier they are performed, when needed, the better. These are major surgical procedures that require a completely aseptic technic and the hands of an expert.

3 Prevention of excessive hemorrhage demands the correct treatment of premature separation of the placenta, of placenta praevia (q v) and of postpartum hemorrhage (q v). Intrapartum hemorrhage is due chiefly to unskilled obstetric intervention: forcible dilation of the cervix producing lacerations, awkward application of forceps inflicting gashes, or the use of solution of pituitary during the second or even the first stage of labor producing cervical and perineal lacerations and even rupture of the uterus. Vaginal hysterectomy or episiotomy, if not skilfully done, may be followed by serious hemorrhage.

TREATMENT

Patients suffering from puerperal sepsis (temperature above 100.5 F on two successive four hour readings) should at once be transferred to the special service and isolated there. A careful general physical examination and a blood culture should be made, the lochia examined, and a culture taken from the vaginal discharge just within the introitus. It is only if the vaginal culture is indeterminate that a culture may be taken from the cervix, with the exercise of the utmost gentleness.

1 Rest must be general as well as local. The patient must not be permitted to get up or even to sit up. She should be free from the annoyances of visitors. She should be kept in Fowler's posture. Sleep may be induced by bromide or phenobarbital (see Insomnia), reinforced by analgesics if there is pain (see Therapy of Pain).

Local rest to the pelvic structures is procured by the uncovered icebag applied to the suprapubic region and by absolute avoidance of internal vaginal or uterine douches and of enemas. Powerful cathartics are taboo. Liquid petrolatum is admissible. No pelvic examinations should be made and the uterus should not be manipulated from the abdomen, as any of these disturbances may favor extension of the infection. If the lochia are profuse and foul, the patient should be placed in the high Fowler position. Ergot and solution of pituitary are given only if bleeding occurs. Otherwise they are contraindicated, as they disturb the rest of the uterus. If the infection remains localized within the uterus (endometritis), most of the patients return to normal within a few days.

When abdominal distention and tenderness set in, the icebag is replaced by large hot stupes over the abdomen. These must not be so heavy as to make the patient

uncomfortable. A rectal tube may help in allowing gas to escape from the bowel.

The appearance of the symptoms of ileus call for the management of that condition (q v). Gastric lavage or the Levine tube are used for vomiting.

2 Therapy of fever (q v) is instituted. This consists most eminently of good nursing. Bedclothes must be changed as often as necessary because of excessive perspiration.

When the patient is seriously sick her fluid balance should be maintained by forcing liquids, particularly fruit juices by mouth, and only if this channel becomes unavailable because of the demands of absolute peritoneal rest should parenteral administration of fluid be resorted to, e g, phlebotoclysis of 2.5 per cent dextrose in half strength (0.425 per cent) Physiologic Solution of Sodium Chloride. One should aim to maintain an elimination of 1,000 cc of urine in the twenty-four hours.

The importance of maintaining the stock of sodium chloride in the patient's system must not be overlooked. When this becomes low, as indicated by absence of chloride in the urine or its presence in very small amounts (0.3 per cent or less), the administration of salt in the form of broths and of Ringer's solution by mouth or of Physiologic Solution of Sodium Chloride by hypodermoclysis is demanded, or, if the deficiency is great, by intravenous injection of hypertonic salt solution.

If acidosis is present or threatened (if the urine is persistently acid to methyl red or if acetone or diacetic acid appears in the urine), carbohydrate administration is demanded, by mouth if possible, or by phlebotoclysis of 10 per cent dextrose if necessary. Alkali should, if possible, be given by mouth in sufficient amounts to render the urine alkaline (at least to methyl red), and, if this method of administration is impossible, 5 per cent sodium bicarbonate solution or Lactate Ringer's (Hartman's) solution should be injected intravenously until this change occurs. The alkali administration must be discontinued if the urine turns thymolphthalein blue. If sugar appears in the urine when dextrose phlebotoclysis is demanded, the simultaneous administration of insulin (see Diabetes Mellitus) is indicated.

3 Immunization is produced. (a) Blood transfusion is very valuable not only if anemia is present but also as a stimulant to the immunity reactions. Usually from 300 to 350 cc of whole blood is given every three or four days. It is especially indicated in anaerobic streptococcal infection, which is the most common cause of thrombophlebitis.

(b) Specific antiserum should be resorted to at the earliest possible moment, as soon as the bacteriologic diagnosis can be made. This may demand diphtheria antiserum (see Therapy of Diphtheria) or Welch bacillus antiserum (see Therapy of Gas Bacillus Infection). Most commonly it is hemolytic streptococcus infection that in its early stages demands 40 cc of the streptococcus antiserum being given intravenously or intramuscularly, to be repeated daily for the next two days. Usually 100 or 120 cc of the serum has proved sufficient. The antisera are of no value in the late stages of any of these infections.

(c) Vaccines may be of value in the subacute and chronic stages of streptococcal infection. But they probably have no advantage over nonspecific protein therapy in its various forms. For this stage of infec-

tion heat is of great value such as that derived from hot douches or the therapeutic lamp. Diathermy may be used in the quiescent period of an infection, although the ultra-short wave current may be used earlier.

The intravenous use of various dyes has not been found of definite value. The colloidal metals are not commonly used because of their cost and their probable lack of value.

(d) Arsphenamine is indicated in rather small therapeutic dosage in the nonspecific spirochetal mixed infections. It has been claimed by some that it is a stimulant to leukocyte production.

4. Surgery has a narrow field of usefulness in the treatment of puerperal sepsis. A posterior colpotomy is indicated for pelvic abscess. Hysterectomy is occasionally indicated for abscess of the uterus wall. Drainage through the abdominal wall as well as through the vagina may be of great aid in an ascending peritonitis. The ligation of veins in thrombophlebitic processes has not been successful; the usual conservative measures having been found more effective. In the presence of puerperal sepsis, curettement is dangerous.

DISCUSSION OF PREVIOUSLY PUBLISHED ARTICLES

THERAPY OF ARTERIAL THROMBOSIS OF THE EXTREMITIES

To the Editor—In THE JOURNAL April 6, page 1229, there was an excellent discussion of the therapy of arterial thrombosis of the extremities by Dr. G. W. Scupham. One inaccuracy in the text is, I believe, of sufficient importance to be corrected. The author describes Goldflam's test for arterial circulation as consisting of "observing the color of the foot while the recumbent patient raises the extended leg rapidly." The original publication by Goldflam (*Neurol Zentralbl* 29, 2, 1910) describes the test as a flexion and extension of the feet while they are maintained in the horizontal position. The test that I described in THE JOURNAL May 11, 1929, page 1571, which has proved reliable in the opinion of many observers, consists of an observation of the plantar surfaces of the feet while the patient flexes and extends both feet with the legs maintained in the vertical position.

Plantar ischemia as elicited by my test has been found to be of considerable importance in the diagnosis of arterial obstruction in the extremities.

SAUL S. SAMUELS, M.D., New York.

[A copy of this communication was submitted to Dr. Scupham, who replies.]

To the Editor—In regard to the criticism by Dr. Saul S. Samuels of the article on the therapy of arterial thrombosis of the extremities, I wish to say that he is quite correct. It is regrettable that this escaped correction when the paper was submitted to me for approval.

Furthermore, periarterial sympathectomy should not have been included in the discussion. When it was mentioned in my lecture on which this paper was based, it was only to mention that it was anatomically incorrect.

GEORGE W. SCUPHAM, M.D., Chicago.

THERAPY OF VARICOSE VEINS AND ULCERS

To the Editor—The article on the therapy of varicose veins and ulcers from the Cook County Hospital, appearing in the February 16 issue of THE JOURNAL, is so comprehensive and clear that it seems in order to note a few points which are not in accord with current thought.

On page 560 the article reads: "No one, of course, would undertake injection treatment of veins in the presence of fresh phlebitis." Tavel in 1907 advised injection in the presence of

phlebitis to help in its healing (*Berl klin Wchnschr* 44, 181, 1907). I have injected above areas of acute phlebitis in many ambulant patients and have always noted quicker disappearance of the local inflammation.

The warnings on systemic contraindications to the sclerosing injections is in my opinion too formidable. I have recently reviewed one thousand consecutive cases of varicose veins treated at the Boston City Hospital. Out of this group there were 375 patients with serious systemic disease including diseases of the heart, lungs and kidneys. There were no mishaps attributable to the injections. As for focal infection, very few patients indeed would be treated if those with septic teeth or tonsils should be eliminated (*The Treatment of Varicose Veins. Is Systemic Disease a Contraindication?* THE JOURNAL, June 8, p. 2577).

On page 561 is the statement that the ligations should be carried out "at the junction of the upper and middle thirds of the thigh." I have recently considered this point in detail and have come to the conclusion, as have others before me, that the site of election is at the saphenofemoral junction. To operate below this point is to invite almost certain recurrence (*Surg, Gynec & Obst* 59, 916 [Dec.] 1934).

EDWARD ALLEN EDWARDS, M.D., Brookline, Mass.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
PAUL NICHOLAS LEECH, Secretary

DINITROPHENOL NOT ACCEPTABLE FOR N N R

The actions of various nitro derivatives of phenol and naphthol as accelerators of metabolism have been studied for the past fifty years. Cazeneuve and Lepine¹ in 1885 described the increase in the metabolism of dogs given dinitronaphthol. They showed that the administration of large doses was followed by vomiting, fever, hyperpnea and death. Rigor mortis set in almost immediately. A few years later Gibbs and Reichert² reported similar observations with the use of dinitrophenol. During the war many cases of dinitrophenol poisoning occurred among French munition workers. The poisoning, which was often severe and sometimes fatal, was of such common occurrence that a special pharmacologic investigation was undertaken. The results of these studies have been reported by Magne, Mayer and Plantefol³.

These workers showed that 1, 2, 4 dinitrophenol increased the oxidation in the tissues of various species of animals and man. They found that the site of the action of the drug was peripheral and that the oxygen consumption of the animal could be increased to twelve times its normal value. These changes were accompanied by hyperpnea and fever. For various species of animals the fatal dose was about 50 mg. per kilogram of body weight, regardless of the mode of administration.

The administration of the drug was followed by a rapid disappearance of glycogen from the liver and muscles, and the development of hyperglycemia. The nitrogen excretion was unaffected. In fatal cases rigor mortis developed early. Degenerative changes in the liver and kidneys were found. Heymans and Bouckaert⁴ showed that the actions of 2, 4 dinitronaphthol are similar to those of dinitrophenol. In 1933 Taunter

3. Magne, Henri, Mayer, Andre, Plantefol, Lucien, Guerbet, Maurice, Georges, J. and Vies, Fred. Etudes sur l'action du dinitrophenol 1,2,4 (Thermol). *Ann. de physiol. et de physiochem. biol.* 7, 269, 1931, S:1, 1932.

4. Heymans, C. and Bouckaert, J. J. Hyperthermic and Cardio-vascular Actions of Dinitro-naphthol in the Dog. *Arch. internat. de pharmacodyn. et de therap.* 35, 63, 1928. Heymans, C. The Influence of Some New Nitroderivatives on the Cellular Metabolism and on the Body Temperature. *J. Pharmacol. & Exper. Therap.* 51:144 (June) 1934.

and Cutting and their co-workers⁵ confirmed much of the work previously reported by the French and Belgian workers. They found, in agreement with previous investigators, that dinitrophenol can increase the oxygen consumption of animals to more than ten times the basal values. The rise in body temperature was found to be secondary to the acceleration in metabolism and was not prevented by the destruction of the brain or spinal cord, or by complete curarization. They concluded, as had Magne, Mayer and Plantefol, that the mechanism of action of dinitrophenol was peripheral. Accompanying the decrease in the liver and muscle glycogen, the concentrations of sugar and lactates in the blood and lactates in the muscle increased. The total carbohydrate disappearing accounted for less than half of the oxygen consumption. This finding, together with a decrease in the respiratory quotient, indicated that fat in addition to carbohydrate was oxidized. The increased amounts of oxygen consumed were carried to the tissues by means of an increased minute volume of circulatory blood and of a greater arteriovenous oxygen difference. Little or no change in the blood pressure and pulse rate was observed. Neither anoxemia nor acidosis was found to develop as long as the respiratory and circulatory mechanisms kept pace with the oxygen consumption. Animals were found to develop no tolerance to the drug. The fatal dose for various species of animals, regardless of the mode of administration, was about 20 to 30 mg per kilogram of body weight.

Death in experimental animals resulted from (1) direct circulatory depression, (2) hyperpyrexia, and (3) acidosis and anoxemia. No effective antidote was found. Tainter and Cutting were unable to find any significant pathologic alteration in liver or kidneys. Rigor mortis set in at once in fatal cases in animals. The actions of the drug in men resembled closely those in animals when equivalent doses were used.

Single doses of from 3 to 5 mg per kilogram of body weight increased the metabolic rate from 20 to 30 per cent in the first hour. After about twenty-four hours the metabolism gradually fell, reaching the previous normal level on the third day. No untoward effects were observed in eight patients even after the two months of daily administration. Single doses of between 5 and 10 mg per kilogram caused no changes in temperature, pulse or respiration, but the patients perspired copiously. In doses of 10 mg per kilogram, dinitrophenol increased the temperature 3 degrees C or more; the respirations were increased markedly. The authors considered the latter doses too dangerous for routine use.

Nine patients given from 3 to 5 mg of the drug per kilogram daily for prolonged periods lost weight without resort to dietary restrictions.⁶ No undesirable symptoms were observed. The authors concluded that dinitrophenol may be useful in the treatment of obesity, hypothyroidism and similar depressed metabolic states.⁷ Because of the possible dangers from the use of the drug in patients, they suggested that the drug be used only under strictly controlled conditions. Accompanying this report of Cutting, Mehrtens and Tainter in *THE JOURNAL*, warning was issued both in a report of the Council on Pharmacy and Chemistry⁷ and in editorial comment⁸ against the uncontrolled administration of the drug. Despite these warnings dinitro-

phenol has been used extensively in the treatment of obesity and not always with the necessary precautions. During the past year the Stanford Clinic supplied physicians and patients, on physicians' prescriptions, more than 1,200,000 capsules of the drug of 0.1 Gm each. It is estimated that 4,500 patients in California alone were treated in one year and that probably 100,000 persons have used the drug in this country since its introduction for the treatment of obesity.⁹ About twenty commercial concerns are furnishing dinitrophenol or mixtures in which this drug is the active principle.⁹ Some smaller concerns have sent samples of the drug unsolicited to physicians and in the accompanying literature have minimized the dangers of its use.

It is not surprising, therefore, that undesirable and even serious toxic manifestations of the drug have been reported.¹⁰ The most common of these is a maculopapular erythematous eruption of the skin reported in 7 per cent of 113 cases treated by Tainter, Stockton and Cutting.¹⁰ Skin disorders were common in the French munition workers poisoned with the drug during the war. Similar toxic manifestations have been reported by Anderson, Reed and Emerson,¹¹ Haft,¹² Dintenfass,¹³ Sidel,¹⁴ Frumess,¹⁵ Hirsch¹⁶ and Jackson and Duvall.¹⁷ Matzger¹⁸ found skin tests to be of no value in predicting skin sensitivity to dinitrophenol. The development of chronic ear infection resulting largely from vascular congestion produced by the drug has been reported.¹³ Itching, swelling of the mucous membranes and disturbances in smell and taste functions were noted by Haft and by Jackson and Duvall.

Haft and Sidel both observed evidence of liver damage following therapeutic doses of dinitrophenol.

Bohn,¹⁹ Silver,²⁰ and Hoffman, Butt and Hickey²¹ have reported cases in which agranulocytic angina developed following the ingestion of the drug.

Up to the present time six deaths following the administration of dinitrophenol have been reported.²² In two of these especially large doses were taken, but in two others the amounts administered did not exceed the dose of 5 mg per kilogram recommended by Tainter and his co-workers. In a third case the dose of the drug was 107 mg per kilogram an amount not before considered to be fatal. In most of the patients, death occurred within twenty-four hours of the onset of toxic symptoms such as dizziness, dyspnea, fatigue, pyrexia and excessive perspiration. Rigor mortis set in promptly after death. In the

case of Poole and Hanning,²² examined after death, degenerative changes in the liver and kidneys were found. There was segmentation and pigmentation of the cardiac muscle, the small blood vessels of the mucosa of the stomach were markedly distended and in places there were small hemorrhages. Essentially similar changes were reported by Tainter and Wood.²² De Chatel and Motike²³ recently have offered evidence of cardiac damage induced by administration of dinitrophenol in animals.

It has been indicated repeatedly in editorial comments in *THE JOURNAL*²⁴ that the sale of dinitrophenol should be restricted to physicians' prescriptions and that the widespread use of the drug in the treatment of obesity should await further study in laboratories and clinics. The use of the drug should be limited to carefully selected cases. Patients with diabetes, nephritis and diseases of the liver and heart should not be given the drug. To treat a mild chronic condition such as obesity with a toxic agent capable of inducing serious injury and death appears to be unjustified. Silver²⁵ in twenty-four carefully studied cases was unable to induce any loss in weight without restricting the diet of the patients. It would appear therefore, that if the loss in weight is employed as an index of the amounts of dinitrophenol required (as indeed it will be unless the administration is rigorously supervised by physicians aware of the dangers) many further cases of toxicity will occur. Strang and Evans²⁶ have found dinitrophenol of questionable practical value in weight reduction. In Germany an official warning regarding the danger of dinitrophenol has been issued.²⁷ According to a report in the *Canadian Medical Association Journal*²⁷ obesity has been included in the list of conditions for which remedies cannot be sold in Canada. Dinitrophenol, therefore, would be barred from sale by the Food and Drugs Act of Canada. It has been suggested, further, that dinitrophenol be put on the Poison List in England thus prohibiting the sale of the drug except on medical prescriptions.²⁸ It is suggested that similar restrictions be placed on the sale of dinitrophenol and reducing mixtures containing dinitrophenol in this country and that the use of the drug be restricted to selected patients under the observation of properly trained physicians. The use of dinitrophenol by all others should await further careful experimentation in the laboratory.

The Council voted that dinitrophenol and brands of dinitrophenol be not accepted for inclusion in New and Nonofficial Remedies and authorized the publication of the foregoing report, which explains the Council's position in this matter.

SODIUM ARSPHENAMINE AND SODIUM DIARSENOL OMITTED FROM N N R

The acceptance of Sodium Diarsenol (Diarsenol Co., Inc.), a brand of sodium arspenamine, expires with the close of 1935. When the matter came before the Council for reconsideration, the referee expressed doubt that it was in the interest of medicine to retain the preparation in New and Nonofficial Remedies any longer.

Sodium arspenamine was devised a number of years ago because of reactions due to the difficulty of proper alkalization of arspenamine. At that time it was thought that this preparation dissolved in distilled water corresponds to the alkaline solution of arspenamine. The use of sodium arspenamine has steadily declined. Not only is it not used generally by syphilologists but it is not mentioned in many of the more recent textbooks.

On the recommendation of the referee the Council deemed it advisable to send a questionnaire to a number of syphilol-

ogists asking their views as to the value of sodium arspenamine. The letter contained the following questions:

- Are you using sodium arspenamine at the present time?
- Do you consider it to be of value in present-day therapy?
- Are you of the opinion that the use of this drug is unwarranted or objectionable?

The view expressed in the replies received was practically unanimous that the drug deserves no place in present-day syphilis therapy.

The Council therefore voted to omit sodium arspenamine and the accepted brand, Sodium Diarsenol, from New and Nonofficial Remedies.

When the foregoing statement of the Council's consideration of Sodium Diarsenol was transmitted to the Diarsenol Company Incorporated, the firm replied:

"Inasmuch as the sale of Sodium Diarsenol has dropped to a negligible amount we are willing to remove all reference to Sodium Diarsenol from our future advertising matter."

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

CITY DAIRY COMPANY PASTEURIZED HOMOGENIZED MILK

Distributor—City Dairy Company, South Bend, Ind.

Description—Bottled, pasteurized, homogenized milk.

Preparation—Milk of 35 per cent minimum fat content, obtained from tuberculin tested herds under government and company inspection, is tested, pasteurized by the standard holding method (61 C for thirty minutes), homogenized under 1,500 pounds pressure, cooled and filled in bottles by the usual procedure (*THE JOURNAL*, Sept 1, 1934, p 681).

Analysis (submitted by manufacturer)—

Total solids	per cent
Fat	13 2
	4 2

Calories—0.7 per gram, 20 per ounce.

Claims of Manufacturer—The cream does not separate. The curd formed in the stomach is softer than that from unhomogenized milk.

DIADEM PATENT FLOUR

Manufacturer—Noblesville Milling Company, Noblesville, Ind.

Description—Patent flour prepared from soft winter wheat, bleached.

Manufacture—Soft winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in *THE JOURNAL*, June 18, 1932, page 2210. Chosen flour streams are blended, and bleached with a mixture of benzoyl peroxide and calcium phosphate (one-half ounce per barrel).

THIN MASTER BREAD SLICED

Manufacturer—Zinsmaster Baking Company, Minneapolis.

Description—Sliced white bread made by the sponge dough method (method described in *THE JOURNAL*, March 5, 1932, p 817), prepared from patent flour, water, sweetened condensed whole milk, sucrose, shortening, sodium chloride, yeast, corn and soya bean flours, and a yeast food containing calcium acid phosphate, ammonium sulphate, sodium chloride, potassium bromate, potassium iodate and corn starch.

SATURDAY JULY 6 1935

LENGTHENING OF LIFE IN PERNICIOUS ANEMIA AND DIABETES

In the application of vital statistics to medical problems there are many opportunities for misinterpretation. The misuse "in certain quarters" of the mortality statistics for diabetes mellitus and pernicious anemia to disprove the claim of discovery of effective remedies has recently been pointed out by an expert statistician.¹

The opposition of certain groups to experimental research has gathered support by the citing of the relatively static mortality from these two diseases since the introduction of insulin and of liver therapy. Enlightened thinkers will scarcely accept this view, but it has remained to Stocks¹ to show the fundamental unreliability of the evidence. He points out that the remedies employed are claimed to be curative only so long as treatment is continued. Therefore every patient under treatment for either of these two diseases must eventually die of one of three groups of causes: (1) a relapse of the disease due to failure to use a reliable and potent remedy and to continue its use with the necessary regularity, (2) some infectious process or acute disease such as influenza or some general disease such as cancer, or (3) some localized disease affecting a vital organ such as the heart, lung or kidney. In the event of death falling in the first or third group, it is usually assigned to the original disease and the effect would be to postpone the age at which it occurred. The deaths classed under the second group must be relatively few compared with the others and hence would not be of great statistical importance.

In taking a hypothetical chronic disease for which a remedy of specific nature but effective only on continuous administration is discovered, the first effect would be to lower the gross mortality for a few years. For simplicity, it may be supposed that the average duration of life after diagnosis of the hypothetical disease was originally two years. The result of the new treatment was to increase this to ten years for cases arising at ages of from 15 to 25, to nine years at ages

of from 25 to 35, to eight at from 35 to 45, and so on to four years at the age of 75 or over. According to this scheme there would be no change in the total deaths, but in the period just following introduction of the new treatment there would be at first a rapid fall in total annual deaths, and during that period the number of persons suffering from the disease in the community would increase year by year until stability between incidence and deaths was reached. The deaths, after an initial fall, would begin to rise again until this condition of stability was attained. The net result, then, would be not to reduce the mortality materially but to prolong life to a later age.

When the diabetes and pernicious anemia mortality was analyzed on this basis, the total mortality and age distribution following the introduction of insulin and of liver therapy were found to follow this pattern to a remarkable degree. Thus the important result of modern treatment of these diseases has been the prolongation of life rather than absolute reduction in mortality. The improved health and usefulness accruing to patients in these groups, so treated, and the addition of several years to the working period of their lives, is a great achievement.

MUSHROOM POISONING

The often uncritical enthusiasms engendered by the approach of summer warrants the renewed reminder that not all of nature's products are beneficent friends of man. The most deadly species of mushroom, *Amanita phalloides*, which causes more than 90 per cent of the deaths from mushroom poisoning, thrives from early June until the first autumn frosts. The flavor of this mushroom is reported to be delicious.¹ The young specimens are the most poisonous and are also most apt to be mistaken for the edible forms by the inexperienced mycologist. Other persons, even less prudent, may ingest toxic varieties after trying various "tests" on them. One of the common kitchen examinations consists in placing a piece of bright silver in the utensil while the plants are cooking. If the silver is not tarnished, the mushrooms are considered safe for consumption. The efficacy of this worthless test is believed in by an astounding number of people.

Some of the fatalities observed in this country due to mushroom poisoning are caused by another variety of mushroom, *Amanita muscaria*. This species also is common in all parts of the United States. The action of the toxins from this type of mushroom is, apparently, more rapid than is that of the poisons present in the various forms of *Amanita phalloides*. Thus there are in general two types of mushroom poisoning that may be encountered: the so-called rapid type (mycetismus nervosus), due to *Amanita muscaria*, and the delayed type (mycetismus cholericiformis) caused by the

¹ Stocks, Percy. The Lengthening of Life by Modern Therapy in Pernicious Anemia and Diabetes. Brit. M. J. 1:1013 (May 18) 1935.

¹ Legal Medicine and Toxicology, edited by Peterson, Frederick Haines, W. S. and Webster, R. W. Philadelphia: W. B. Saunders Company, 1923.

various forms of *Amanita phalloides*. The rapid type of poisoning occurs within one to three hours after the ingestion of the fungi and is characterized by excessive salivation, perspiration and lacrimation. Nausea, vomiting, severe abdominal pains and diarrhea also occur. The pupils are contracted and convulsions and coma are seen in the severe cases. The mortality is low and the patients respond well to proper treatment¹. The delayed type of mycetismus results from the ingestion of mushrooms belonging to the *Amanita phalloides* group. The onset is delayed until five to sixteen hours or more after the ingestion of the fungi. Abdominal pains are severe, and nausea and vomiting may be extreme. Diarrhea is nearly always present and the patients are generally prostrated from the outset. Jaundice nearly always occurs and renal damage is frequent. Symptoms resulting from damage to the central nervous system are usually present. The mortality in this type of poisoning is at least 50 per cent.

Four cases of poisoning by *Amanita phalloides* have been recently reported². The value of this contribution is increased by the authors' presentation of complete pathologic studies in two fatal cases. Extreme degenerative changes were found in the parenchymal cells of the liver and to a lesser extent in the tubular epithelium of the kidneys. In both patients there was a severe widespread damage to the central nervous system. The brains were congested and edematous, and on microscopic section degenerative changes were observed in the cells of the cortex, hypothalamus, cerebellum and brain stem. Fat was found almost everywhere throughout the brain, and there were scattered areas of perivascular infiltration with lymphocytes. All the signs and symptoms that were observed in the two fatal cases could be explained by the pathologic changes observed. This report supplements the already extensive literature on the subject of mushroom poisoning, in addition, it serves to emphasize again the salient facts of this important subject.

THE USE OF ESTROGENIC SUBSTANCE IN TERMINATING HUMAN PREGNANCY

The rapid advances that have recently been made in the elucidation of the physiologic roles of ovarian, placental and pituitary principles have led to extensive clinical use of many endocrine products in gynecology and obstetrics. Probably the most widely employed are the estrogenic preparations, these have been tried in a variety of disorders. As is common with glandular products, the original hopes engendered by a too ready transference to human beings of effects obtained in animals have been substantiated in only small degree. Reference to the commendably conservative article by Novak¹ in the series on Glandular Physiology and

Therapy now appearing in *THE JOURNAL* reveals how limited are the actual clinical indications for estrogenic substance.

Depending on time relationships and dosage, estrogenic substance may be either supplementary or antagonistic to the corpus luteum hormone, progesterin, in the effects on uterine mucosa, it is antagonistic to progesterin (and to the gonadotropic principle of pregnancy urine also) in the effects on the irritability of the uterine musculature (Estrogenic substance augments contractility, while progesterin and the gonadotropic principle depress it). As Allen² states, "large doses of estrogenic substance may override the effects of progesterin and progesterin can inhibit the effects of estrogenic substance." In pregnancy the various endocrine factors concerned in the proper maintenance of this complex process are in an intricate equilibrium, which changes continuously from the time of maturation of the ovum until parturition. A marked imbalance in one or more of the factors concerned might conceivably terminate or prolong pregnancy.

Thus, many attempts have been made to interrupt pregnancy in animals by injection of estrogenic preparations,³ or to prolong it by administration of progesterin or the gonadotropic factor of pregnancy urine. In rats, guinea-pigs and rabbits, pregnancy (particularly early pregnancy) can readily be interrupted by estrogenic preparations or can be prolonged by progesterin or the gonad-stimulating factor. However, attempts to transfer to human beings the results obtained in animals with theelin or theelol have usually failed⁴. As Allen² has pointed out, this is not surprising in view of the large amounts of estrogenic substance known to be present in women during pregnancy. However, the questions of dosage (in view of the low potency of the estrogenic preparations available until recently) and other physiologic factors involved have remained unsolved.

The report just published by Robinson, Datnow and Jeffcoate⁵ of Liverpool is therefore of great importance. These authors investigated the effects of estrogenic preparations of high potency (10,000 and 100,000 international units per cubic centimeter) in terminating pregnancy at various stages from seven weeks to term. Estrogenic substance was used in multiple doses, either alone or followed after an interval of about 100 hours from the first dose by one or more doses of posterior pituitary extract (which has been found to be synergistic with theelin in its action on the uterine musculature) and/or quinine.

2 Vander Veer J B and Farley D L. Mushroom Poisoning (Mycetismus). *Arch Int Med* 55:772 (May) 1935.

1 Novak Emil. Glandular Physiology and Therapy. The Therapeutic Use of Estrogenic Substances. *J A M A* 104:1815 (May 18) 1935.

In twelve cases of early pregnancy, from seven to fourteen weeks in duration, in which therapeutic abortion was indicated, estrogenic substance in a total dosage of from 50,000 to 6,800,000 international units, followed in all but one case by posterior pituitary extract and/or quinine, failed to produce abortion in a single instance.

In contrast to the effects in early pregnancy, in ten cases varying in duration from thirty to forty weeks, labor occurred in five after administration of total amounts of estrogenic substance of from 80,000 to 1,600,000 international units, followed in all but one of the five cases by posterior pituitary extract and/or quinine. However, as the authors point out, in two of the successful cases it appears possible that labor may have occurred spontaneously (one other case in which the patient was at term, should probably also be included among those that gave "doubtful" responses).

In one case of twins with hydramnios in the thirty-fifth week, the patient responded to 50,000 units of estrogenic substance with onset of labor ninety hours after the first injection. Another patient in preeclampsia also in the thirty-fifth week, responded to 20,000 units (the fetus in this case was anencephalic).

The most promising results were obtained in missed abortion (not, as the authors emphasize, in incomplete abortion). In ten of a group of twelve cases of intra-uterine death of the fetus, expulsion of the uterine contents occurred following total dosages of from 40,000 to 2,430,000 units. This occurred even when the dead fetus had been retained for many weeks. In six of these cases estrogenic substance was used alone, in four, posterior pituitary extract and quinine or castor oil were given in addition. This is of particular interest, as the authors point out, in that Spielman, Goldberger and Frank⁶ have noted that the amount of estrogenic substance in the blood is markedly decreased following intra-uterine death of the fetus.

In four cases of uterine inertia, administration of total amounts of from 20,000 to 1,300,000 units of estrogenic substance led to enhanced uterine contractility.

Robinson and his associates conclude from their studies that estrogenic substance, when administered near term "may or may not induce premature labour, but that it is not a reliable means of induction." They point out that "it is an especially unsuitable method for cases in which it is necessary to bring on labor immediately because of the uncertain interval (up to seven or eight days) that intervenes between the commencement of treatment and the onset of expulsive contractions." They believe that the results in missed abortion are quite encouraging.

Thus it appears that in woman, estrogenic substance is chiefly of value in enhancing the irritability of the

uterus late in pregnancy and that, at least in the dosages used and by the methods employed, it is of little value in inducing abortion during the early stage (seven to fourteen weeks) covered by the investigation of Robinson and his collaborators. It must not be overlooked, however, that the work discussed, while valuable, is only a preliminary investigation. Much more needs to be known about the physiology of human pregnancy and particularly about the complex endocrine equilibriums involved.

Current Comment

DERMAL ABSORPTION OF VITAMIN D

Several years ago, experiments¹ on rabbits and rats were reported suggesting that vitamin D was absorbed through the skin. Irradiated impure cholesterol suspended in cottonseed oil and applied to the depilated skin on the backs of the experimental animals completely protected them from rickets. Recently similar results have been obtained in rats administered viosterol by inunction. One investigator² has observed that the application of viosterol in either a liquid petrolatum or a wax base to the tail alone permitted the absorption of sufficient amounts of the antirachitic factor to prevent the development of rickets. The possibility of the oral ingestion of some of the material was precluded by carefully encasing the animal's tail in a glass tube. Further confirmatory evidence³ has been obtained on rats fed a standard rachitogenic diet and given inunctions of viosterol in an ointment base on areas of skin from which the hair had been removed by a sulphide depilatory. Both roentgenograms and "line tests" showed that the animals thus treated were completely protected from rickets, whereas controls receiving inunctions of irradiated liquid petrolatum developed the condition. The subsequent dermal administration of viosterol to the rachitic control animals promptly promoted normal bone calcification. The fact that the irradiated liquid petrolatum controls developed rickets precludes the possibility that the results obtained with viosterol were due to the absorption of the irradiated lipid solvent, which then activated ergosterol in the tissues by secondary radiation. Thus it appears probable that vitamin D itself is absorbed directly from the skin. The practical value of this method of administering vitamin D remains to be determined. It may prove useful in infants and in subjects lacking the ability to utilize lipids administered orally. From the available data it appears probable, however, that the process of dermal absorption as compared with enteral absorption may not be an economical one. Although no attempt has been made to compare quantitatively the required doses by the two methods of administration, the amount employed daily in the latter experiments just described was forty-five times the recognized effective oral dose.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE EIGHTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 10 14, 1935

(Concluded from page 2372 volume 104)

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 o'clock by Dr. Reginald Fitz, Boston, in the absence of Dr. George R. Minot, Boston. Alphonse M. Schwitalla, St. Louis, was nominated for Associate Fellowship in the American Medical Association.

Drs. Simon S. Leopold and Louis M. Lieberman, Philadelphia, presented a paper on 'Further Data on Artificial Pneumothorax in Experimental Lobar Pneumonia.'

Drs. Francis G. Blake, Marion E. Howard and Winifred S. Hull, New Haven, Conn., presented a paper on 'Artificial Pneumothorax in the Treatment of Lobar Pneumonia.'

These two papers were discussed by Drs. Alfred Stengel, Philadelphia, Jesse G. M. Bullowa, New York, and Harold Brunn, San Francisco.

Dr. W. R. Kennedy, Montreal, read a paper on 'Renal Amyloidosis.' Discussed by Drs. Henry A. Christian, Boston, Walter de M. Scriven, Montreal, and S. Edward King, New York.

Dr. Emanuel Libman, New York, presented the Frank Billings Lecture, entitled 'Some Aspects of Endocarditis with Special Reference to the Subacute Variety.'

Dr. W. F. Hamilton, Montreal, read a paper on 'Pleural Shock.' Discussed by Drs. Joseph A. Capps, Chicago, Victor S. Randolph, Phoenix, Ariz., and Jonathan C. Meakins, Montreal.

Dr. W. P. Warner, Toronto, read a paper on 'Factors Causing Bronchiectasis, Their Clinical Application to Diagnosis and Treatment.' Discussed by Drs. David T. Smith, Durham, N. C., and Harold Brunn, San Francisco.

THURSDAY, JUNE 13—AFTERNOON

Dr. James B. Collip, Montreal, read a paper on 'The Anti-hormone Theory in Relation to Anterior Pituitary Physiology.' Dr. David P. Barr, St. Louis, read a paper on 'Recent Advances in Knowledge of the Relationship of the Pituitary to Ovarian Hormones.'

These two papers were discussed by Drs. Elmer L. Sevringhaus, Madison, Wis., Archibald C. Campbell, Montreal, Joseph C. Aub, Boston, and Harold E. Simon, Birmingham, Ala.

Dr. Duncan Graham, Toronto, read the Canadian chairman's address.

Dr. Lewellys F. Barker, Baltimore, read the Osler Oration, entitled 'Osler in America.'

Dr. Lloyd F. Craver, New York, read a paper on 'A Clinical Survey of the Etiology of Cancer.'

Drs. Jacob Furth, H. W. Ferris and Paul Reznikoff, New York, presented a paper on 'Relation of Experimental Leukemia of Animals to Human Leukemia.'

Dr. W. Edward Chamberlain, Philadelphia, read a paper on 'Modern Concepts of Roentgen Therapy in Cancer.'

These three papers were discussed by Drs. G. E. Richards, Toronto, T. R. Waugh, Montreal, Louis K. Diamond, Boston, and Charles C. Lund, Boston.

FRIDAY, JUNE 14—AFTERNOON

The following officers were elected: chairman, Dr. William J. Kerr, San Francisco; vice chairman, Dr. C. L. Andrews, Atlantic City, N. J.; secretary, Dr. Joseph T. Wear, Cleve-

land; executive committee, Dr. C. T. Stone, Galveston, Texas; Dr. George R. Minot, Boston; Dr. William J. Kerr, San Francisco.

Dr. E. B. Bradley, Lexington, Ky., read a report of the Committee on Examinations of the American College of Physicians.

Dr. Walter L. Bierring, Des Moines, Iowa, presented the following resolution:

Resolved That a committee of three, including a chairman, be appointed by the chairman of the Section on Practice of Medicine to discuss with a committee from the American College of Physicians ways and means whereby an examining board comparable to such boards already existing in certain specialties may be set up for the purpose of certification of specialists in internal medicine.

On motion of Dr. Bierring, duly seconded, the resolution was adopted.

Drs. C. A. McKinlay and Hal Downey, Minneapolis, and Joseph Stasney, Rochester, Minn., presented a paper on 'Infectious Mononucleosis.' Discussed by Drs. A. H. Gordon, Montreal, Israel Davidsohn, Chicago, and C. A. McKinlay, Minneapolis.

Dr. Walter R. Campbell, Toronto, read a paper on 'Dietary Factors in Health and Disease.' Discussed by Dr. Henry A. Christian, Boston.

Dr. R. F. Farquharson, Toronto, read a paper on 'The Importance of Rest and Liver Therapy in the Treatment of Subacute Combined Degeneration of the Cord.' Discussed by Drs. William B. Castle, Boston; H. H. Hyland, Toronto; Roy R. Grinker, Chicago; and R. F. Farquharson, Toronto.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. John L. Yates, Milwaukee.

Dr. John L. Yates read a paper on 'Therapeutic Significance of Normal and Morbid Formation and Distribution of Non-cellular (Plasma) and Cellular Constituents of Blood and of Lymph.'

Dr. William B. Castle, Boston, read a paper on 'Treatment of Anemia in Surgical Conditions, with Especial Reference to Deficiency States.'

Dr. John S. Lawrence, Rochester, N. Y., read a paper on 'Variations in the Number of Leukocytes in Normal and Morbid States.'

Dr. Charles H. Best, Toronto, read a paper on 'Regulation of Blood Sugar.'

Dr. E. C. Kendall, Rochester, Minn., read a paper on 'Thyroxine and the Hormone Elaborated by the Adrenal Cortex.'

Dr. Cecil K. Drinker, Boston, read a paper on 'The Relation of Lymph Circulation to Streptococcal Infection.'

Dr. Reuben L. Kahn, Ann Arbor, Mich., read a paper on 'Antigens and Antibodies.'

Dr. Jonathan C. Meakins, Montreal, presented a summary from an internist's point of view.

Dr. G. W. Crile, Cleveland, presented a summary from a surgeon's point of view.

These nine papers were discussed by Drs. William Dameshek, Boston, and William B. Castle, Boston.

THURSDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr William E Gallic, Toronto

The following papers were read as a symposium on "Anomalies in Blood Formation"

Dr E S Mills, Montreal "Pathology and Differential Diagnoses of Blood Dyscrasias Amenable to Treatment by Splenectomy"

Dr C A Doan, Columbus, Ohio "Hemolytopoietic Equilibrium and Emergency Splenectomy"

Dr A T Bazin, Montreal "Surgical Procedure and After-Care"

Dr William E Gallic, Toronto "End Results"

These four papers were discussed by Drs Irvin Abell, Louisville, Ky, G M Curtis, Columbus, Ohio, B K Wiseman, Columbus, Ohio, H C Thompson, New York, William Dameshek, Boston, E B Krumbhaar, Philadelphia, and C A Doan, Columbus, Ohio

The following papers were read as a symposium on "Anomalies in Blood Distribution"

Dr David D Berlin, Boston "Total Thyroidectomy for Intractable Heart Disease." Discussed by Drs John Hepburn, Toronto, and David D Berlin, Boston

Dr Max M Peet, Ann Arbor, Mich "Operative Treatment of Hypertension" Discussed by Drs George J Heuer, New York, Guza de Takats, Chicago, and Max M Peet, Ann Arbor, Mich

Dr Louis G Herrmann, Cincinnati "Nonoperative Treatment of Inadequate Peripheral Distribution of Blood" Discussed by Drs H M Elder, Montreal, N E Freeman, Boston, and Louis G Herrmann, Cincinnati

Dr E J McGrath, Cincinnati "Experimental Peripheral Gangrene" Discussed by Drs D W G Murray, Toronto, and E J McGrath, Cincinnati

FRIDAY, JUNE 14—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr John L Yates, Milwaukee

The following officers were elected chairman, Dr Howard M Clute, Boston, vice chairman, Dr William F Rieuhoff, Baltimore, secretary, Dr Henry Cave, New York, delegate Dr Fred W Rankin, Lexington, Ky, alternate, Dr Harold Brunn, San Francisco

On motion by Dr Fred W Rankin, Lexington, Ky, seconded, it was voted that the Executive Committee of the Section on Surgery, General and Abdominal, appoint a board of five members to meet with the American Surgical Association, the American College of Surgeons and the Pacific Coast Association to discuss the advisability of establishing a qualifying board in general surgery, the preliminary and special qualifications to be expected of candidates and the type of examination to be given leading to qualification

The following papers were read as a symposium on "Toxemia and Septicemia, Chronic Appendicitis, Manifestations of Cholelithiasis and Treatment of Jaundiced Patients"

Dr D T Fraser, Toronto "Staphylococcus Antitoxin and Toxoid"

Dr W S Keith, Toronto "Clinical Use of Staphylococcus Antitoxin and Toxoid"

Dr W J Merle Scott, Rochester, N Y "Principles of Treatment of Septicemia."

Dr J R Reeves, Indianapolis "Infections by Anaerobic Gas-Forming Bacilli"

These four papers were discussed by Drs George A Ramsay, London, Ont, David Tillerson Smith, Durham, N C, and D T Fraser, Toronto

Dr L C Smard, Montreal, read a paper on "Neuro-Appendicopathy" Discussed by Drs H W Cave, New York, and L C Smard, Montreal

Dr Robert M Zollinger, Boston, read a paper on "Significance of Pain and Vomiting in Cholelithiasis"

Dr E S Judd, Rochester, Minn, read a paper on "Transfusions of Blood and Intravenous Administration of Dextrose in Jaundiced Patients"

These two papers were discussed by Drs F K Boland, Atlanta, Ga, W J Merle Scott, Rochester, N Y, and E S Judd, Rochester, Minn.

SECTION ON OBSTETRICS, GYNECOLOGY
AND ABDOMINAL SURGERY

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr James R McCord, Atlanta, Ga

Drs Aaron E Kanter, Carl P Bauer and Arthur H Klawans, Chicago, presented a paper on "A New Biologic Test for Hormones in Urine as Applied to Various Clinical Problems" Discussed by Drs Fredericka F Freytag, Dayton, Ohio, Charles Mazer, Philadelphia, and Aaron E Kanter, Chicago

Drs F H Falls, Julius L Lackner and Leon Krohn, Chicago, presented a paper on "The Effect of Progestin and Estrogenic Substance on Human Uterine Contractions, and the Value of Progestin in the Prevention of Habitual and Spontaneous Abortions" Discussed by Drs Samuel R M Reynolds, Brooklyn, Emil Novak, Baltimore, J P Pratt, Detroit, and Leon Krohn, Chicago

Drs S F Haines and R D Mussey, Rochester, Minn, presented a paper on "Certain Menstrual Disturbances Associated with Low Basal Metabolic Rates" Discussed by Drs J C Litzenberg, Minneapolis, T J Williams, University, Va, and R D Mussey, Rochester, Minn

Dr John R Fraser, Montreal, read the Canadian chairman's address, entitled "Maternal Mortality and Morbidity"

Drs P Brooke Blind, Arthur First and Leopold Goldstem, Philadelphia presented a paper on "Clinical Investigation of Endocrine Sterility"

Dr Paul Titus, Pittsburgh, read a paper on "Sterility Analysis of Causes and Treatment"

These two papers were discussed by Drs N R Kretschmar, Ann Arbor, Mich, Emil Novak, Baltimore, Isidor C Rubin, New York, B R Almqvist, Pittsburgh, A D Campbell, Montreal, and Arthur First, Philadelphia

THURSDAY, JUNE 13—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr John R Fraser, Montreal

Dr James R Goodall, Montreal read a paper on "Toxemia of Pregnancy A Clinical Study" Discussed by Drs J C Janney, Boston and Katherine Kuder, New York

Dr H B Van Wyck, Toronto read a paper on "The Clinical Significance of Weight Changes in Pregnancy" Discussed by Drs Murray L Brandt, New York, G D Royston, St Louis, and A W Bingham, East Orange, N J

Dr John Mann, Toronto, read a paper on "The Mechanism of Rotation in Occiput Posterior Positions" Discussed by Drs E L King, New Orleans, W E Caldwell, New York, Joseph B De Lee, Chicago, J B Jacobs, Washington D C, and John Mann, Toronto

Dr James R McCord, Atlanta, Ga., read the chairman's address, entitled "Syphilis and Pregnancy A Clinical Study of 2,500 Cases"

Drs Harvey B Matthews and Vincent P Mazzola, Brooklyn, presented a paper on "The Intravenous Use of Hypertonic Dextrose in Obstetrics and Gynecology An Experimental and Clinical Study" Discussed by Drs James R Miller, Hartford, Conn, Joseph B De Lee, Chicago, Charles W Pavey, Columbus, Ohio, and Harvey B Matthews, Brooklyn

Dr Harold L Morris, Detroit, read a paper on "Hematuria as a Complication of Pregnancy" Discussed by Drs John M Bergland, Baltimore, and Joseph B De Lee, Chicago

FRIDAY, JUNE 14—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr James R McCord, Atlanta, Ga

The following officers were elected chairman, Dr Lyle G McNeile, Los Angeles, vice chairman, Dr W J Carrington, Atlantic City, N J

The following papers were read as a symposium on "Obstetric Anesthesia"

Drs Beatrice E Tucker and Harry B W Benaron, Chicago "Parasacral Pudendal and Local Infiltration Anesthesia in Obstetrics"

Drs S A Cosgrove, Perry O Hull and William J Gleason, Jersey City, N J "Spiritual Anesthesia, with Particular Reference to Its Use in Obstetrics"

Dr Wesley Bourne, Montreal "Vinyl Ether Obstetric Anesthesia for General Practice"

Dr Ralph T Knight, Minneapolis "Cyclopropane Anesthesia in Obstetrics"

Dr Edward W Beach, Philadelphia "Ethyl Ether, Chloroform, Nitrous Oxide and Ethylene Anesthesia in Obstetric Analgesia and Anesthesia"

Drs James T Gwathmey New York, and C O McCormick, Indianapolis "Rectal Ether and Oil"

These six papers were discussed by Drs R A Gaughan, Hazelton, Pa Lyle G McNeile, Los Angeles, Joseph B De Lee, Chicago, Carrol J Fairro Cincinnati H F Beckman, Indianapolis E Mabel H Otis, Moline, Ill, Harry B W Benaron, Chicago, S A Cosgrove, Jersey City, N J, Wesley Bourne, Montreal Ralph T Knight, Minneapolis, C O McCormick Indianapolis, and James T Gwathmey, New York

SECTION ON OPHTHALMOLOGY

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr Arthur J Bedell, Albany, N Y

Dr W Gordon M Byers Montreal, Canadian chairman, presented greetings from Canada

Dr Arthur J Bedell, Albany, N Y, read the chairman's address

Mr Leslie Paton London England the guest of honor read a paper on "Papilledema and Optic Neuritis A Retrospect"

Dr Martin Cohen, New York read a paper on "Inflammatory Exophthalmos in Catarrhal Disorders of the Accessory Sinuses" Discussed by Drs H C Naffziger, San Francisco, Gilbert Horrax, Boston, Alexander E MacDonald Toronto Thomas B Holloway Philadelphia, Joseph D Kelly, New York, and Martin Cohen, New York

The following resolutions were read by Dr Frederick H Verhoeff, Boston, for the Executive Committee to be presented to the House of Delegates Thursday afternoon

WHEREAS There have been many complaints regarding the action of some ophthalmologists in giving lectures to and consulting with opticians and optometrists and

WHEREAS It is universally conceded that to care for the diseases and conditions of the human eye demands the unusual knowledge of a graduate physician who has been especially prepared and

WHEREAS The eye is an integral part of the body and

WHEREAS No one but a physician so trained should be permitted to diagnose treat or prescribe for eye conditions and

WHEREAS Lecture address or any other form of instruction to opticians and optometrists by ophthalmologists is not only a breach of the Principles of Medical Ethics which control our professional relationships but is also to the detriment of the ocular health of the public by giving it a false sense of security and

WHEREAS General health and ocular comfort depend on the best medical care therefore be it

Resolved That the Section on Ophthalmology of the American Medical Association declares that it is unethical for any member of the American Medical Association to give lectures or courses of instruction to or consult with any one not associated with the actual medical service and be it further

Resolved That the House of Delegates of the American Medical Association be asked to make a ruling to this effect

On motion of Dr Verhoeff, duly seconded and carried, the resolutions were adopted

It was voted that the section recommend to the House of Delegates, through the Judiciary Council that Mr Leslie Paton, London England be made an honorary member of the American Medical Association

Dr Frank E Burch, St Paul read a paper on "Association of Ectopia Lentis with Arachnodactyly" Discussed by Drs William Zentmayer Philadelphia Ralph I Lloyd Brooklyn M N Beigelman Los Angeles Edward Jackson, Denver, and Frank E Burch St Paul

Dr Jonas S Friedenwald Baltimore, read a paper on "The Treatment of Anisophoria" Discussed by Drs Walter B Lancaster, Boston Francis H Adler, Philadelphia, Conrad Berens, New York, and Jonas S Friedenwald, Baltimore

THURSDAY, JUNE 13—AFTERNOON

Dr Conrad Berens, New York, read a paper on "The Causes of Blindness in Children Their Relation to Preventive Ophthalmology" Discussed by Drs Albert D Frost, Columbus, Ohio, S W Newmayer, Philadelphia, Thomas B Holloway, Philadelphia, Harry S Gradle, Chicago, E V L Brown, Chicago, Mr Leslie Paton, London, England, Mr Lewis H Carris, National Association for the Prevention of Blindness, New York, Trygve Gundersen, Boston, V M Hicks, Raleigh, N C, and Conrad Berens, New York

Drs Norman P Scala, Washington, D C, and Ernest A Spiegel, Philadelphia, presented a paper on "The Pupillary Reactions in Combined Lesions of the Posterior Commissure and of the Pupillo dilator Tracts" Discussed by Drs Harry S Gradle, Chicago, C W Rutherford, Iowa City, and Ernest A Spiegel Philadelphia

Dr Alexander E MacDonald, Toronto, read a paper on "Kinetic Stereoscopes or Stereoscopic Phenomena of a Moving Observer" Discussed by Drs Frederick H Verhoeff, Boston, Alfred Cowan, Philadelphia, and Alexander E MacDonald, Toronto

Drs Phillips Thygeson and William F Mengert, Iowa City, presented a paper on "The Virus of Inclusion Conjunctivitis Further Observations" Discussed by Drs Clyde A Clapp, Baltimore, and Phillips Thygeson, Iowa City

Dr Ruby Kathryn Daniel, Rochester, Minn, read a paper on "Allergy and Cataracts Deductions Drawn from Clinical Studies" Discussed by Drs Alan C Woods, Baltimore, Derrick T Vail Jr, Cincinnati, W R Buffington, New Orleans, C Ulysses Moore, Portland, Ore, and Ruby K Daniel, Rochester, Minn

At the Demonstration Session the following were shown

Dr Frederick H Verhoeff, Boston, presented a new needle holder for ophthalmic and other delicate surgery

Dr Albert D Ruedemann, Cleveland, presented a camera for photography of the conjunctival vessels under high magnification

Dr Walter B Lancaster, Boston, presented some astigmatic charts

Dr Clifford B Walker, Los Angeles presented new equipment for the galvanic treatment of separated retina

Dr Mark J Schoenberg, New York presented an improved exophthalmometer and a biomicroscope for use in delicate surgical operations

Dr Sidney L Olsho Philadelphia, presented bifocal lenses for patients with myopia

Dr Conrad Berens, New York, presented forceps for use in surgery of the ocular muscles

Dr John Green, St Louis, presented a simplified ophthalmoscope for Dr William Henry Luedde, St Louis

Dr Harvey E Thorpe, Pittsburgh presented a forceps for removal of lead shot from the vitreous.

Dr Richard Townley Paton, New York, presented a moving picture, following adjournment of the session, entitled "Cine-fusionometer A Treatment and Diagnostic Instrument"

FRIDAY, JUNE 14—AFTERNOON

Dr Albert C Snell, Rochester, N Y, presented the report of the Committee on Compensation Tables The report was accepted and the committee continued

Dr Edward Jackson, Denver, presented the report of the American Committee on Optics and Visual Physiology The report was accepted

The report of the Committee on the Knapp Testimonial Fund was presented by the treasurer, Dr Parker Heath, Detroit The report was accepted

Dr G P Guibor, Chicago, gave a short report of his work on squint

The Committee on Awarding the Knapp Medal reported that it was unanimously decided not to make any recommendation this year The report was accepted

The report of the Committee on the American Board of Ophthalmology was read by Dr Walter B Lancaster, Boston. The report was accepted

The report of the Committee on National Museum of Ophthalmic Pathology was presented by Dr Jonas S Friedenwald, Baltimore. The report was accepted.

The report of the Committee from the Section to Cooperate with the National Committee for the Prevention of Blindness was presented by Dr Thomas B Holloway, Philadelphia. The report was accepted.

The report of the Committee on Scientific Exhibit from the Section was presented by Dr Georgiana Dvorak Theobald, Oak Park, Ill. The report was accepted.

The Report of the Committee to Confer with the National Conference on Nomenclature of Disease was presented by Dr Walter B Lancaster, Boston. It was voted that Dr Lancaster be delegated to receive future inquiries on nomenclature but that the committee be discharged with thanks.

Dr Emory Hill, Richmond, Va., reported as delegate to the House of Delegates.

The report of the Committee on Museum of Ophthalmic History was read by Dr Parker Heath, Detroit.

The report of the Committee on Ophthalmic Standards was presented by Sanford R Gifford, Chicago. It was voted that the report be accepted and the committee continued.

The following officers were elected: chairman, Dr John Green, St. Louis; vice chairman, Dr Albert C Snell, Rochester, N. Y.

Dr Clifford B Walker, Los Angeles, was appointed as member of the American Board of Ophthalmology for four years and Dr John Green to serve for one year.

Dr William Henry Luedde, St. Louis, was reappointed to fill the vacancy on the American Committee on Optics and Visual Physiology.

The following were appointed to serve on the Committee on Scientific Exhibit: Dr Georgiana Dvorak Theobald, Oak Park, Ill.; chairman, Dr Albert N B Leinoine, Kansas City, Mo.; and Dr Parker Heath, Detroit.

The Ophthalmic Research Medal of the American Medical Association was awarded by Dr Frederick Verhoeff, Boston, to Dr Jonas S Friedenwald, Baltimore.

The following members were elected to serve as the Knapp Medal Award Committee: Dr George E de Schweinitz, Philadelphia; Dr William E Shahan, St. Louis; and Dr F Plumizy Calhoun, Atlanta, Ga.

The members stood in silence in tribute to the memory of those who passed away during the year and particularly to the memory of Dr William Campbell Posey.

Dr Edward Jackson, Denver, read a paper on 'The Control of Myopia.' Discussed by Drs Albert C. Snell, Rochester, N. Y.; F. T. Tooke, Montreal; S. W. Newmayer, Philadelphia; Meyer Wiener, St. Louis; Joseph I. Pascal, New York; Walter B. Lancaster, Boston; and Edward Jackson, Denver.

Dr Francois Badeaux, Montreal, read a paper on "Herpes Ophthalmicus. I. Radiotherapy in Herpes Zoster Ophthalmicus and Herpetic Keratitis." Discussed by Drs Eugene P. Pendergrass, Philadelphia; Laura A. Lane, Ann Arbor, Mich.; and Francois Badeaux, Montreal.

Dr Trygve Gundersen, Boston, read a paper on 'Herpes Ophthalmicus. II. Herpes Corneae with Special Reference to Its Treatment with Tincture of Iodine.' Discussed by Drs Everett L. Goar, Houston, Texas; Jonas S. Friedenwald, Baltimore; and Trygve Gundersen, Boston.

Drs S. J. Beach and William R. McAdams, Portland, Maine, presented a paper on "Intracapsular Extraction in the Average Practice: Report of One Hundred Cases." Discussed by Drs Walter R. Parker, Detroit; John Green, St. Louis; J. W. Millette, Dayton, Ohio; Frederick H. Verhoeff, Boston; and William R. McAdams, Portland, Maine.

Dr Arthur M. Culler, Dayton, Ohio, read a paper on 'Artificial Fever Therapy of Ocular Syphilis.' Discussed by Drs William L. Benedict, Rochester, Minn.; Elmer L. Whitney, Detroit; and Arthur M. Culler, Dayton, Ohio.

Dr Melvorton E. Trainor, Los Angeles, read a paper on "Trainor Operation for Lid Ptosis." Discussed by Drs Arnold Knapp, New York; E. C. Ellett, Memphis, Tenn.; and Melvorton E. Trainor, Los Angeles.

SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9:05 by the chairman, Dr John J. Shea, Memphis, Tenn.

The chairman announced the death of Dr John W. Carmack, Dr William V. Mullin and Dr D. Campbell Smyth during the past year and the members arose in tribute to their memory.

Dr Joseph Beck, Chicago, of the Board of Examiners, reported that the board had examined 162 candidates during the past year. Two extra examinations were held. Dr Beck called attention to the report from the Board of Examiners to the Advisory Board of the Medical Specialties.

On motion by Dr Horace Newhart, duly seconded, it was voted that the following resolution be presented to the House of Delegates Thursday afternoon:

WHEREAS Certain agents and contributors of electric hearing devices have offered to physicians a commission or bonus for referring to them hard of hearing persons to whom they effect a sale, therefore be it

Resolved By the Section on Laryngology, Otolaryngology and Rhinology of the American Medical Association that it condemns as unethical and unfair to the purchaser the practice on the part of any agent or distributor of a hearing device who offers to pay to a physician or any one not an authorized agent any commission or bonus for referring a person to whom he makes a successful sale. The acceptance of such commission by a physician is interpreted as a violation of the principles of ethical practice and be it further

Resolved That it is the sense of this section that the use of audiometers in the hands of persons other than regularly qualified physicians be restricted to the measuring of hearing acuity for the purpose of detecting hearing loss and for selecting or constructing hearing aids best suited to the special needs of the individual hard of hearing person.

It was moved by Dr Joseph Beck, Chicago, duly seconded and carried that David J. Goodfriend, DDS, Philadelphia, and Oscar Koenig, DDS, Newark, N. J., be recommended to Associate Fellowship.

Dr D. E. S. Wishart, Toronto, read the address of Dr W. J. McNally, Montreal, Canadian chairman, entitled "Milestones in the Recent Development of Our Knowledge of Hearing and Balancing."

Mr Norman Patterson, London, England, read a paper on 'Carcinoma of the Larynx. A Plea for Conservative Surgery in Certain Cases in Which Laryngectomy Might Be Considered Necessary.' Discussed by Drs H. B. Orton, Newark, N. J.; Louis H. Clerf, Philadelphia; and Mr Norman Patterson, London, England.

Dr David L. Thomson, Montreal, read a paper on "Aspects of Mineral Metabolism." Discussed by Drs Ralph A. Fenton, Portland, Ore.; J. A. Babbitt, Philadelphia; and David L. Thomson, Montreal.

Dr John B. McMurray, Washington, Pa., read a paper on "A Study of Clinical Cases with Vertigo as a Cardinal Symptom." Discussed by Drs K. A. MacKenzie, Halifax, N. S.; D. E. S. Wishart, Toronto; H. R. Slack, Jr., Baltimore; George E. Shambaugh, Jr., Chicago; and John B. McMurray, Washington, Pa.

Dr Leroy A. Schall, Boston, read a paper on "Neoplasms Involving the Middle Ear." Discussed by Drs B. H. Shuster, Philadelphia; Joseph Beck, Chicago; George M. Coates, Philadelphia; Frank R. Spencer, Boulder, Colo.; and Leroy A. Schall, Boston.

THURSDAY, JUNE 13—MORNING

Dr John J. Shea, Memphis, Tenn., read the chairman's address, entitled "The Clinical Consideration of the Morphology of the Sinuses."

Dr Edward Clay Mitchell, Memphis, Tenn., read a paper on "The Pediatric View of Otolaryngology." Discussed by Drs Percy Wright, Montreal; H. Marshall Taylor, Jacksonville, Fla.; Simon L. Ruskin, New York; and Edward Clay Mitchell, Memphis, Tenn.

Dr Hector Mortimer, Montreal, read a paper on "The Hormone Factors Involved in the Evolution, Development and Growth of the Paranasal Sinuses." Discussed by Drs James B. Collip, Montreal; Charles W. Dunn, Philadelphia; and Hector Mortimer, Montreal.

Dr Gregor W. McGregor, Toronto, read a paper on "Bone Proliferation in Accessory Sinuses. A Pathologic Study." Dis-

cussed by Drs Ralph A Fenton, Portland Ore, S R Skillern Jr, Philadelphia H Z Samcnov, Los Angeles, K M Houser, Philadelphia, and Gregor W McGregor, Toronto

The section went into executive session. The following resolution was read by Dr Burt R Shurly, Detroit, delegate, and adopted

WHEREAS The medical profession has an interest in public safety and in the preservation of life and the preventing of injury and

WHEREAS, The motor vehicle has been responsible for an ever increasing loss of life and limb and

WHEREAS The damage to humanity may be curtailed by careful physical examination of motor vehicle drivers including stringent test of color blindness sight and hearing as well as other physical and mental qualifications therefore be it

Resolved That the Section on Laryngology Otology and Rhinology request the House of Delegates to appoint a special committee to study such legislation as may be required to regulate and prescribe appropriate tests for the licensing of all drivers of motor vehicles and recommend such uniform legislation in the several states

Dr George E Hodge Montreal read a paper on "The Relationship of Bronchiectasis to Paranasal Sinus Infection" Discussed by Drs E G Gill, Roanoke, Va Herman J Moersch, Rochester, Minn. Frank R. Spencer Boulder, Colo, Myron Metzenbaum, Cleveland and George E Hodge, Montreal

Dr Frederick M Law, New York read a paper on "Errors in Interpretation of Roentgenograms in Otolaryngology" Discussed by Drs W E Chamberlain Philadelphia, S R Skillern Jr, Philadelphia, and Frederick M Law, New York

FRIDAY JUNE 14—MORNING

The following officers were elected chairman Dr Ralph A Fenton, Portland Ore vice chairman, Dr E M Seydell, Wichita, Kan secretary, Dr Gordon B New Rochester Minn.

Dr Chevalier Jackson, Philadelphia reported for the Committee on Lye Legislation that a model lye bill had been passed in New York. The committee is now at work in states that lack legislation for proper labeling of caustics. It was voted that the report be accepted and a vote of thanks be sent Mr B R Richards, Department of Health, New York.

Dr William P Wherry Omaha read the report of the Committee on the Otorhinologic Hygiene of Swimming for the chairman H Marshall Taylor Jacksonville Fla. It was recommended that children subject to nasal or aural disease who belong to certain organizations such as the Boy Scouts, which require proficiency in swimming in order that the child may retain his membership should be permitted to substitute other physical attainments, on the recommendation of the attending otolaryngologist. The recommendation was adopted. It was voted that thanks be extended to the committee and that the committee be continued.

Dr Gabriel Tucker Philadelphia, presented a new method of removal of foreign bodies from the stomach.

Dr Walter A Wells, Washington, D C., presented a new audiometer.

Dr Horace Newhart Minneapolis called attention to an effective sound testing room on exhibit outside.

Dr Claude C Cody, Houston Texas read a paper on "Brucellosis in Otolaryngology" Discussed by Drs Redvers Thompson Ste Anne de Bellevue Que Walter M Simpson, Dayton, Ohio, Caesar Hirsch, New York and Claude C Cody, Houston, Texas

Drs Chevalier Jackson and Chevalier L Jackson Philadelphia, presented a paper on "Contact Ulcer of the Larynx." Discussed by Drs H S Birkett Montreal, and Gabriel Tucker, Philadelphia

Dr Samuel J Kopetzky New York read a paper on "The Diagnosis and Differential Diagnostic Data of Specific Types of Suppuration in the Petrosal Pyramid" Discussed by Drs J A Sullivan Toronto, Henry K. Taylor New York, Ralph Almour New York Simon L Ruskin, New York and Samuel J Kopetzky, New York

Dr Ernest E Scharfe Montreal read a paper on "The Value of Speech Training in Cleft Palate and Other Mouth Conditions" Discussed by Drs R. R Fitzgerald Montreal V H Kazanjian Boston G M Dorrance, Philadelphia and Ernest E Scharfe, Montreal

Dr M C Myerson, New York, read a paper on "Tuberculosis of the Larynx Requiring Tracheotomy" Discussed by Drs Frank R Spencer, Boulder, Colo, George B Wood, Philadelphia, Gabriel Tucker Philadelphia, Joseph I Kemler, Baltimore, and M C Myerson, New York

SECTION ON PEDIATRICS

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9 15 by the chairman, Dr A Graeme Mitchell, Cincinnati

Dr A Graeme Mitchell, Cincinnati read the chairman's address, entitled "Critical Interpretation of Clinical Observations"

Dr R. G Hoskins, Boston, read a paper on "Progress and Problems in Endocrinology"

Dr Henry F Helmholtz, Rochester, Minn, read a paper on "Therapeutic Results with the Ketogenic Diet in Urinary Infections" Discussed by Dr Edward L Bauer, Philadelphia

Dr Gladys L Boyd, Toronto, read a paper on "Pulmonary Collapse in Children" Discussed by Drs Joseph Stokes Jr, Philadelphia, Joseph S Wall, Washington, D C., and William E Anspach, Chicago

The chairman appointed Drs Clifford Sweet Oakland Calif, and Horton Casparis, Nashville, Tenn, as a resolutions committee

Dr Pearl F Summerfeldt, Toronto, read a paper on "Iron and Its Availability in Foods" Discussed by Dr C. Ulysses Moore, Portland, Ore.

Drs Alan G Brown and Edward A. Morgan, Toronto, presented a paper on "Cyanosis of the New-Born" Discussed by Drs Ethel C Dunham, New Haven Conn, John D Donnelly, Bala-Cynwyd, Pa., and Clifford Sweet, Oakland, Calif

THURSDAY, JUNE 13—MORNING

Dr Franklin P Gengenbach, Denver, read a paper on "When Pediatricians Take Inventory" Discussed by Dr Borden S Veeder, St Louis

Dr Alan G Brown, Toronto, Canadian chairman, addressed the session

Dr Bret Ratner, New York, read a paper on "Milk Allergy and Its Basic Treatment." Discussed by Drs Charles G Kerley, New York, Samuel Goldberg, Philadelphia, Albert H Rowe, Oakland, Calif George Piness, Los Angeles, and Franklin P Gengenbach, Denver

Dr Henry P Wright, Montreal, read a paper on "Allergy and Immunity in Childhood Tuberculosis" Discussed by Drs J C Gittings, Philadelphia, M James Fine, Newark, N J, and A Graeme Mitchell, Cincinnati

Dr George L Waldbott, Detroit, read a paper on "The Allergic Theory of So Called Thymus Death" Discussed by Drs B S Kline, Cleveland, and A Graeme Mitchell, Cincinnati

Dr Frederick F Tisdall Toronto, read a paper on "Inadequacy of Present Dietary Standards" Discussed by Drs Walter B Stewart, Atlantic City, N J, Harry H Donnelly, Washington, D C, Clifford Sweet, Oakland, Calif, and Herbert L Elias, Rockville Centre, N Y

Dr Lawrence T Royster, University, Va, read a paper on "Body Type in Negro Children" Discussed by Drs Howard C Carpenter Philadelphia, Frank Lee Bivings Atlanta, Ga. Harold C Stuart, Boston, and Emil Bogen, Olive View, Calif

FRIDAY, JUNE 14—MORNING

The following officers were elected chairman Dr Horton Casparis, Nashville, Tenn, vice chairman, Dr Hugh Dwyer, Kansas City, Kans, secretary, Dr Ralph M Tyson, Philadelphia, delegate, Dr William Weston, Columbia, S C, alternate, Dr A Graeme Mitchell, Cincinnati representative on Scientific Exhibit, Dr F Thomas Mitchell, Memphis, Tenn

On motion of Dr A H Parmelee, Oak Park, Ill., seconded and carried, thanks were extended to Dr Isaac A Abt for his term of service as delegate

Dr F Thomas Mitchell Memphis Tenn, presented the report of the Committee on Scientific Exhibit.

Dr Isaac A Abt Chicago, presented the report of the delegate to the House of Delegates. The report was adopted.

Dr Frank C Neff of Kansas City presented the Report of the Committee on the Jacoby Fund. On motion regularly made and seconded, it was voted that the report be adopted.

Drs Arthur Hawley Parmelee, Oak Park, Ill., and Louis J Halpern, Chicago, presented a paper on "The Diagnosis of Congenital Syphilis." Discussed by Drs Joseph Yampolsky, Atlanta, Ga., Henry H Perlman, Philadelphia, and Arthur Hawley Parmelee, Oak Park, Ill.

Dr Fred W Schlutz, Chicago, read a paper on "Systemic Thrush Infection." Discussed by Drs Isaac A Abt, Chicago, and F W Schlutz, Chicago.

Dr J Norman Henry, Philadelphia, read a paper on "A Study of Immunization Against Scarlet Fever in Charitable Institutions and Public Schools of Philadelphia." Discussed by Drs John A Toomey, Cleveland, P F Lucchesi, Philadelphia, Theodore Melnick, Philadelphia, and J Norman Henry, Philadelphia.

Dr George M Retan, Syracuse, N Y, read a paper on "The Development of the Therapeutic Use of Forced Perivascular (Spinal) Drainage." Discussed by Drs Temple S Fay, Philadelphia, Harry Lowenburg, Philadelphia, Tracy J Putnam, Boston, and George M Retan, Syracuse, N Y.

Drs Maurice Brodie and William H Park, New York, presented a paper on "Active Immunization Against Poliomyelitis Experimental and Human Studies." Discussed by Drs John A Kolmer, Philadelphia, Alton Goldbloom, Montreal, and Maurice Brodie, New York.

Dr Josephine B Neal, New York, read a paper on "Meningococcal Meningitis in Children." Discussed by Drs Bronson Crothers, Boston, Emily P Bacon, Philadelphia, and Josephine B Neal, New York.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr Carl H Greene, New York.

Dr V E Henderson, Toronto, read the Canadian chairman's address, following which he took the chair and presided throughout the afternoon session.

Drs C W Chapman and C A Morrell, Ottawa, Ont., presented a paper on "Standardization and Potency of Digitalis Preparations."

Drs H E Rykert and John Hepburn, Toronto, presented a paper on "The Intravenous Use of Strophanthin in the Treatment of Auricular Fibrillation."

Dr Charles W Greene, Columbia, Mo., read a paper on "Response of Coronary Vessels to Various Organic Drugs."

These three papers were discussed by Drs E E Nelson, Washington, D C, E Fullerton Cook, Philadelphia, Harry Gold, New York, Tasker Howard, Brooklyn, William D Stroud, Philadelphia, V A Lapenta, Indianapolis, F G Atwood, New Haven, Conn., Louis F Bishop Jr, New York, and Benjamin Jablons, New York.

Dr E M Watson, London, Ont., read a paper on "Clinical Experiences with Wheat Germ Oil (Vitamin E)." Discussed by Drs E D Plass, Iowa City, Paul Titus, Pittsburgh, and C W Chapman, Ottawa, Ont.

THURSDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 05 by the chairman, Dr Carl H Greene, New York. Dr V E Henderson, Toronto, Canadian chairman, presided during part of the session.

On motion by Dr Leonard G Rowntree, Philadelphia, duly seconded and carried, the following were nominated for Associate Fellowship in the American Medical Association: William C MacTavish, New York, Clarence W Muehlberger, Chicago, and Marie Severac, Philadelphia.

Dr Carl H Greene, New York, read the chairman's address, entitled "The Personal Element in Therapeutics."

Dr Herman O Mosenthal, New York, read a paper on "Hyperglycemia: Evaluation in the Treatment of Diabetes Mellitus." Discussed by Drs Elhott P Joslin, Boston, Edwin J Kepler, Rochester, Minn., W S Collins, Brooklyn, Charles T Maxwell, Sioux City, Iowa, and A A Herold, Shreveport, La.

Drs Arthur Grollman and W M Firor, Baltimore, presented a paper entitled "Experimental Studies on Replacement Therapy in Adrenal Insufficiency." Discussed by Drs Edwin J Kepler, Rochester, Minn., R G Hoskins, Boston, and Leonard G Rowntree, Philadelphia.

Drs Leonard G Rowntree and J H Clark, Philadelphia, and A M Hanson, Faribault, Minn., presented a paper on "The Biologic Effects Following the Continuous Administration of Pineal Extract to Successive Generations." Discussed by Dr R G Hoskins, Boston.

Dr D Roy McCullagh, Cleveland, read a paper on "The Pharmacology of Testicular Hormones." Discussed by Drs William E Lower, Cleveland, R G Hoskins, Boston, and James B Collip, Montreal.

Drs Maurice L Tainter, Windsor C Cutting, Andrew B Stockton and E Hines, San Francisco, presented a paper on "The Metabolic and Anobesity Actions of Dinitrophenol." Discussed by Drs Maurice Bruger, New York, and Frank A Evans, Pittsburgh.

Dr Tom D Spies, Cleveland, read a paper on "The Treatment of Pellagra." Discussed by Drs Henry L Bockus, Philadelphia, W H Sebrell Jr, Washington, D C, L K Riggs, New Brunswick, N J, A A Herold, Shreveport, La., and Russell L Haden, Cleveland.

FRIDAY, JUNE 14—AFTERNOON

The following officers were elected: chairman, Dr C D Leake, San Francisco, vice chairman, Dr N C Gilbert, Chicago, secretary, Dr Russell L Haden, Cleveland, delegate, Dr Cary Eggleston, New York, alternate, Dr N M Keith, Rochester, Minn., executive committee, Dr C D Leake, San Francisco, Dr Carl H Greene, New York, and Dr John H Musser, New Orleans.

Dr Clark W Heath, Boston, read a paper on "The Clinical Significance of Problems of Absorption in the Human Gastro-Intestinal Tract." Discussed by Drs Thomas T Mackie, New York, T Grier Miller, Philadelphia, Samuel Goldschmidt, Philadelphia, and Harold S Connamacher, Newark, N J.

Dr Kenneth I Melville, Montreal, read a paper on "Comparative Effects of Pressor and Oxytocic Fractions of Posterior Pituitary Extract on Blood Pressure and Intestinal Activity." Discussed by Dr D Roy McCullagh, Cleveland, and Kenneth I Melville, Montreal.

Dr Franklin A Weigand, Philadelphia, read a paper on "The Diuretic Action of Intravenous Sodium Dehydrocholate." Discussed by Drs B B Vincent Lyon, Philadelphia, Abraham Cantarow, Philadelphia, and Franklin A Weigand, Philadelphia.

Drs Norman M Keith and Melvin W Binger, Rochester, Minn., presented a paper on "The Diuretic Action of Potassium Salts." Discussed by Drs M Herbert Barker, Chicago, Carl H Greene, New York, and Melvin W Binger, Rochester, Minn.

Drs Joseph Kovacs, Irving S Wright and Leslie Saylor, New York, presented a paper on "A Pharmacologic and Therapeutic Study of Certain Choline Derivatives." Discussed by Drs V E Henderson, Toronto, and Isaac Starr, Philadelphia.

Dr Fred E Angle, Kansas City, Kan., read a paper on "Treatment of Acute and Chronic Brucellosis." Discussed by Dr Harold J Harris, Westport, N Y.

SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9 20 by the chairman, Dr Elias P Lyon, Minneapolis, who introduced Dr Ludvig Hektoen, honorary chairman, to preside during the remainder of the session.

The following papers were read as an anniversary program by founders of the section:

Dr Ludvig Hektoen, Chicago, "The Specificity of Streptococci" (honorary chairman's address).

Dr Walter L Biering, Des Moines, Iowa, "Development of Pathology Since 1900."

Dr George H Simmons, of Miami, Fla., one of the founders of the section, made a brief address.

Dr James B Herrick, Chicago "Internal Medicine Since 1900"

Dr George Blumer, New Haven Conn "Relationship of Pathologic Training to Clinical Medicine"

THURSDAY, JUNE 13—MORNING

The following were appointed by the chair as a nominating committee Drs Eugene R Whitmore, Washington D C, A C Ivy, Chicago, and H J Corper, Denver

The following were nominated to Associate Membership in the Association Dr Paul R Cannon, professor of pathology University of Chicago Paul L Day Ph D professor of biologic chemistry, University of Arkansas Fayetteville Ark. Frank A Hartman, Ph D professor of physiology Ohio State University, Columbus Ohio, and Dr William H Woglom experimental pathologist New York

Dr Elias P Lyon, Minneapolis read the chairman's address entitled "I Am Automatic"

The following papers were read as a symposium on 'The Autonomic Nervous System'

Dr Albert Kuntz, St Louis 'Essential Anatomy'

Dr Anton J Carlson, Chicago 'Essential Physiology'

Dr D E Jackson, Cincinnati 'Essential Pharmacology'

Drs Loyal Davis and Lewis J Pollock, Chicago 'The Role of the Autonomic Nervous System in the Causation of Pain'

Dr George E Brown Rochester Minn 'Clinical Tests of the Functions of the Sympathetic Nervous System'

Dr Alfred W Adson Rochester Minn "Indications for Surgery on the Sympathetic Nervous System"

These six papers were discussed by Drs W J Merle Scott, Rochester, N Y Irving S Wright, New York, James C White, Boston, Emmett Lee Jones Cumberland, Md Albert Kuntz St Louis, Anton J Carlson Chicago and Alfred W Adson Rochester, Minn

FRIDAY, JUNE 14—MORNING

The following officers were elected chairman Dr Henry C Swamy, Chicago, vice chairman Dr W L Garrey Nashville, Tenn secretary, Dr J J Moore Chicago delegate Dr David J Davis, Chicago, alternate Dr J J Moore Chicago

The secretary read the following report The committee appointed to consider the possibilities of forming a qualifying board for pathologists in conformity with the desires of the Advisory Board of Medical Specialties of the American Medical Association met at a meeting in Atlantic City, June 7, 1935 They are agreed that such a qualifying board should be formed at this time and recommend that a committee of three or more be appointed to meet with similar committees from the allied societies with power to act in the immediate formation of a Specialty Board in Pathology

J J MOORE, Chicago

E B KRUMBHAAR, Philadelphia

FRANK W HARTMAN Detroit

On the motion of Dr Anton J Carlson Chicago, seconded and carried, the report was approved

Dr William Boyd, Winnipeg, Man it read the Canadian chairman's address, entitled "The Relation of Pathology to Medicine"

Dr E Perry McCullough, Cleveland read a paper on "Post-tive Friedman Tests in Nonpregnant Individuals"

Dr R H Freyberg and L H Newburgh Ann Arbor Mich presented a paper on 'The Choice and Interpretation of Tests of Renal Efficiency' Discussed by Dr Herman O Mosenthal, New York

Dr John A Kolmer, Philadelphia, read a paper on 'Susceptibility and Immunity in Relation to Vaccination in Acute Anterior Poliomyelitis' Discussed by Drs William H Park New York H T Kramer Brooklyn, and John A Kolmer, Philadelphia

Dr Jesse G M Bullowa New York read a paper on 'Reliability of Sputum Typing in the Pneumoniae' Discussed by Drs William H Park, New York S W Sappington, Bryn Mawr Pa, and Jesse G M Bullowa, New York

Dr Charles C Macklin London, Ont, read a paper on "Alveolar Pores and Their Significance in the Human Lung"

Discussed by Drs William Boyd, Winnipeg, Man it, E B Krumbhaar, Philadelphia and Charles C Macklin London, Ont Dr B K Wiseman, Columbus, Ohio, read a paper on "The Nature and Importance of the Reciprocal Cellular Equilibrium That Exists Between Lymphatic and Myeloid Tissues as Revealed by Experimental and Clinical Studies" Discussed by Drs E B Krumbhaar, Philadelphia, and B K Wiseman, Columbus Ohio

Dr Emil Novak Baltimore read a paper on "Sex Determination Sex Differentiation and Intersexuality, with Report of Unusual Case" Discussed by Drs Elias P Lyon, Minneapolis, P M Menlowe McKeesport Pa, Jacob Auslander, New York, and Emil Novak Baltimore

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr H Douglas Singer Chicago

On motion of Dr Walter Freeman, Washington, D C, unanimously carried, Dr C M Hincks New York, and Dr E A Spiegel Temple University Medical School, Philadelphia, were nominated for election to Associate Fellowship in the American Medical Association

Drs Walter Freeman H H Schoenfeld and Claude Moore, Washington D C presented a paper on "Ventriculography with Colloidal Thorium Dioxide" Discussed by Drs Temple S Fay, Philadelphia, R Glen Spurling, Louisville, Ky, Tracy J Putnam, Boston, Hans Reese, Madison Wis, H H Schoenfeld Washington, D C, Claude Moore, Washington D C, and Walter Freeman, Washington, D C

Drs S P Goodhart, B H Balser and Irving Bieber New York presented a paper on "Encephalographic Studies in Extrapyramidal Disease" Discussed by Drs A J Bendick, New York Charles Davison, New York, Tracy J Putnam Boston, and S P Goodhart, New York

Dr Carlo J Tripoli, New Orleans read a paper on "Meningitis A Comparative Study of Various Therapeutic Measures" Discussed by Drs John H Musser New Orleans Josephine B Neal, New York R Glen Spurling Louisville, Ky Peter Bassoe Chicago Alfred Gordon, Philadelphia and Carlo J Tripoli New Orleans

Dr Tracy J Putnam, Boston, read a paper on "Etiologic Factors in Multiple Sclerosis" Discussed by Drs Armando Ferraro, New York, L H Cornwall New York, Roy Grinker, Chicago, and Tracy J Putnam, Boston

Drs William deG Mahoney New Haven, Conn and Donal Sheehan, Manchester England, presented a paper on "Experimental Ptosis in Monkeys and Chimpanzees The Synergic Action of Third Nerve and Cervical Sympathetic" Discussed by Dr R Glen Spurling Louisville, Ky

Dr J A Hannah, Toronto, read a paper entitled "Report of a Case of Alzheimer's Disease with Neuropathologic Observations" Discussed by Drs R P MacKay Chicago Mary B Baughman, Richmond, Va Peter Bassoe Chicago, Hans Wassing Paterson N J, and J A Hannah, Toronto

Dr George W Hall Chicago, read a paper on "Post-Traumatic Narcolepsy" Discussed by Drs Henry W Woltman Rochester Minn., John B Doyle, Los Angeles, and George W Hall, Chicago

THURSDAY, JUNE 13—AFTERNOON

Dr H Douglas Singer read the chairman's address, entitled 'Research in Psychiatry'

Dr Earl D Bond Philadelphia, read a paper on "The Onset in Postencephalitic and Traumatic Behavior Cases" Discussed by Drs Bernard J Alpers, Philadelphia, Bronson Crothers, Boston James P Leake, Washington, D C, and Earl D Bond, Philadelphia

Drs Lloyd H Ziegler and Arthur Knudson, Albany, N Y, presented a paper entitled "A Study of Activity After Recovery from Rickets An Experimental Study" Discussed by Drs Leo Kanner, Baltimore, Frederick F Tisdall, Toronto, Le Roy M A Maeder, Philadelphia, Bronson Crothers, Boston, and Lloyd H Ziegler, Albany, N Y

Dr A T Mathers, Winnipeg, Manlt, read the Canadian chairman's address, entitled "Medicolegal Relationships"

Dr George B Hassin, Chicago, Dr Henry W Woltman, Rochester, Minn, and Dr H Douglas Singer were appointed to act as a committee to nominate officers for the section for the ensuing year

Dr Walter Freeman, Washington, D C, made the following report, as representative of the Section on the American Board of Psychiatry and Neurology

"The American Board of Psychiatry and Neurology was finally organized after the session last year in Cleveland and held two or three meetings during the winter. The Section on Nervous and Mental Diseases is being represented by four members and the American Psychiatric Association and the American Neurological Association each by four members

"During the winter, plans for the certification of specialists were made and the first examination was held June 7 and 8 in Philadelphia. At this time thirty-one candidates were examined. These men all graduated between the years of 1919 and 1929 and were therefore in group 2, which it was decided should be examined. Of those thirty-one candidates, twenty-one were passed, four were conditioned, and six failed

"According to the by-laws of the board, those who are conditioned and those who fail may take subsequent examinations to make up their deficiencies. If this is done within three years, a small fee is charged. If the delay is too long, the application for renewed examination is treated as an original application

"The board plans to hold further examinations this year, one at Christmas time in New York, at the time of the meeting of the Association for Research in Nervous and Mental Diseases, and possibly another in some other city, either before or after that

"In addition to the thirty-one candidates who were examined for the certificate of the board, about forty candidates for certification on the record were acted on at the meeting of the board held in Philadelphia. These men represented those who graduated up to and including 1919, and it was decided that in those individuals no examination was necessary"

Dr Niels L Anthonisen, Belmont, Mass, read a paper on "Depression as a Part of a Life Experience. A Study of Forty Consecutive Cases". Discussed by Drs Earl D Bond, Philadelphia, Lloyd H Ziegler, Albany, N Y, and Niels L Anthonisen, Belmont, Mass

Drs Theophil Klingmann, Ann Arbor, Mich, and William H Everts, New York, presented a paper on "The Intensive Treatment of Morphine Addiction". Discussed by Drs Edwin G Zabriskie, New York, Mieczyslaw Openchowski, Newark, N J, and Theophil Klingmann, Ann Arbor, Mich

Drs C C Burlingame and Carl P Wagner, Hartford, Conn, presented a paper on "The Psychiatric Hospital as an Institution of Learning". Discussed by Drs Edwin G Zabriskie, New York, Lloyd J Thompson, New Haven Conn, and Carl P Wagner, Hartford, Conn

Dr Tom B Throckmorton, Des Moines, Iowa, delegate, made his report

FRIDAY, JUNE 14—AFTERNOON

The following officers were elected: chairman, Dr Hans Reese, Madison, Wis, vice chairman, Dr Percival Bailey, Chicago, secretary, Dr Henry R Viets, Boston, delegate, Dr Tom B Throckmorton, Des Moines, Iowa, alternate, Dr Edward Delehanty, Denver

Dr George W Hall, Chicago, was chosen as a member of the American Board of Psychiatry and Neurology

Drs Samuel Brock, Aaron Bell and Charles Davison, New York, presented a paper on "A Clinical Study of Seven Cases of Nervous Complications Following Spinal Anesthesia. Tissue Study in One Instance". Discussed by Drs E D Friedman, New York, G H Hyslop, New York, C C Nash, Dallas, Texas, and Samuel Brock, New York

Drs Paul C Bucy and Douglas N Buchanan, Chicago, presented a paper on "The Simulation of Intracranial Neoplasm by Lead Encephalopathy in Children". Discussed by Drs Tracy J Putnam, Boston, Hans Reese, Madison, Wis, Roy Grinker, Chicago, L H Loeser, Newark, N J, and Paul C Bucy, Chicago

Drs William Cone and Wilder Penfield, Montreal, presented a paper on "Subtemporal and Suboccipital Myoplastic Crani-

otomy". Discussed by Drs Francis C Grant, Philadelphia, W James Gardner, Cleveland, Max M Peet, Ann Arbor, Mich, and William Cone, Montreal

Dr Francis Grant, Philadelphia, read a paper on "Clinical Aspects and Treatment of Chronic Subdural Hemorrhage." Discussed by Dr Tracy J Putnam, Boston, W James Gardner, Cleveland, Peter Bassoe, Chicago, Walter Freeman, Washington, D C, James W Watts, Philadelphia, C C Nash, Dallas, Texas, A M Kraut, Jersey City, N J, Max M Peet, Ann Arbor, Mich, Edgar A Kahn, Ann Arbor, Mich, and Francis C Grant, Philadelphia

Dr T C Erickson, Montreal, read a paper on "Paroxysmal Neuralgia of the Tympanic Nerve (Jacobson's Nerve)". Discussed by Dr Francis C Grant, Philadelphia

Dr Chalmers H Moore, Birmingham, Ala, read a paper on "Cranio-cerebral Trauma. Pathologic and Clinical Classification". Discussed by Dr Francis C Grant, Philadelphia

SECTION ON DERMATOLOGY AND SYPHILOLOGY

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr Jeffrey C Michael, Houston, Texas

The chairman introduced Dr J F Burgess and Dr Paul Poirier, Montreal, chairman and secretary respectively of the Dermatological Section of the Canadian Medical Association. Dr Burgess and Dr Michael presided jointly during the meetings

Dr Howard Fox, New York, reported for the Committee on the International Dermatological Congress

Dr Jeffrey C Michael, Houston, Texas, read the chairman's address, entitled "Consideration of the More Important Questions of the Etiology and Therapy of Acne Vulgaris"

Drs A M Davidson and P H Gregory, Winnipeg, Manlt, presented a paper on "The So-Called Mosaic Fungus as an Intercellular Deposit of Cholesterol Crystals". Discussed by Drs John Godwin Downing, Boston, S William Becker, Chicago, M F Engman Jr., St Louis, and A M Davidson, Winnipeg, Manlt

Drs Hermann Feit, Elizabeth Ann Laszlo and Frank Vero, New York, presented a paper on "Rosacea Interpreted as a Bacterid from Focal Infection". Discussed by Drs Samuel Ayres Jr, Los Angeles, Myer Solis-Cohen, Philadelphia, John H Stokes, Philadelphia, and Hermann Feit, New York

Dr D E H Cleveland, Vancouver, B C, read a paper on "Lichen Simplex Chronicus"

Drs J M Van de Erve, Charleston, S C, and S William Becker, Chicago, presented a paper on "Functional Studies in Patients with the Neurodermatoses"

These two papers were discussed by Drs Paul A O'Leary, Rochester, Minn, Samuel M Peck, New York, John H Stokes, Philadelphia, Samuel Goldblatt, Cincinnati, Theodore Cornbleet, Chicago, W U Rutledge, Louisville, Ky, Eugene T Bernstein, New York, D E H Cleveland, Vancouver, B C, and S William Becker, Chicago

Dr John H Stokes, Philadelphia, read a paper on "An 'Office' Technic of Treating Functional Neuroses as Complications of Organic Disease, with Special Reference to the Dermatoneuroses". Discussed by Drs Earl D Bond, Philadelphia, S William Becker, Chicago, Elmore B Tauber, Cincinnati, and John H Stokes, Philadelphia

Drs Paul D Foster, Los Angeles, and George M MacKee, New York, presented a paper on "Histogenesis of Aberrant Lesions of Psoriasis". Discussed by Drs Clark W Finnerud, Chicago, Fred Wise, New York, Hermann Feit, New York, George C Andrews, New York, David Bloom, New York, Adolph B Loveman, Louisville, Ky, Marion Z Sulzberger, New York, and Paul D Foster, Los Angeles

THURSDAY, JUNE 13—AFTERNOON

Dr Frank D Weidman, Philadelphia, gave the report of the Scientific Exhibits Committee, stating that there was a balance of \$233 on hand, and as the expenses would not be more than \$50 or \$60 per annum, this would be enough for three or four years, after which time the funds appropriated by the American

Medical Association would be sufficient to cover expenses. Dr Weidman tendered his resignation as chairman of the Scientific Exhibit.

The chairman appointed an auditing committee consisting of Dr Howard Morrow, San Francisco, and Dr Otto H Foerster, Milwaukee, to audit the accounts of the chairman of the Scientific Exhibit.

Dr C Guy Lane, Boston, read the report of the American Board of Dermatology and Syphilology.

Dr J F Burgess, Montreal, read the Canadian chairman's address, entitled "Chronic Gladders in Man."

Dr Frank R Smith Jr, Baltimore, read a paper on "The Treatment of Early and Late Congenital Syphilis in Children. The Results of Treatment in 521 Cases." Discussed by Drs E J Trow, Toronto, Adolph Rostenberg, New York, and Frank R Smith Jr, Baltimore.

Drs Duncan O Poth, Burton F Barney and Udo J Wile, Ann Arbor, Mich., presented a paper on "A Study of Dementia Paralytica and Tabes with Reference to Precocious Development." Discussed by Drs A Benson Cannon, New York, Udo J Wile, Ann Arbor, Mich., S B Hadden, Philadelphia, and Duncan O Poth, Ann Arbor, Mich.

Dr Walter M Simpson, Dayton, Ohio, read a paper on "Artificial Fever Therapy of Syphilis." Discussed by Drs Frank R Menagh, Detroit, Clarence A Neymann Chicago, Albert N B Lemoine, Kansas City, Mo., M F Engman Jr, St Louis, John H Stokes, Philadelphia, Paul A O'Leary, Rochester, Minn., and Walter M Simpson, Dayton, Ohio.

Drs A Benson Cannon and Joycelin H Robertson, New York, presented a paper on "A Study of the Comparative Value of Bismuth and Mercury Compounds in the Treatment of Early Syphilis." Discussed by Drs Harold N Cole, Cleveland, and Samuel Goldblatt, Cincinnati.

Drs Harold N Cole and E A Levin Cleveland, presented a paper on "Intradermal Test for Chancroids with Sterilized Pus from Chancroidal Buboec." Discussed by Drs Eugene F Traub, New York, David Bloom, New York, James L Pipkin, San Antonio, Texas, and Harold N Cole, Cleveland.

Dr John F Madden, St Paul, read a paper on "The Balamitides." Discussed by Drs P H Poirier, Montreal, Joseph V Klauder, Philadelphia, Samuel Ayres Jr, Los Angeles, and John F Madden, St Paul.

FRIDAY, JUNE 14—AFTERNOON

The report of the auditing committee, which found the accounts correct, was received.

Dr Marion B Sulzberger, New York, offered the following motion: That the chairman of this section appoint a committee on which he is to act ex officio, this committee to consist of members of this section to study and report on the ways and means by which American dermatology can most effectively organize in the study and treatment of occupational dermatoses, and how this section can best cooperate with the Section on Industrial and Preventive Medicine and Public Health and with the United States Public Health Service in the formation of a central institute for the cooperative approach to the problems of industrial skin diseases. The motion was seconded and carried, and the chairman announced that the incoming chairman would appoint the committee.

The following officers were elected: chairman, Dr Harry R. Foerster, Milwaukee; vice chairman, Dr John Godwin Downing, Boston; secretary, Dr Jesse Bedford Shelmire, Dallas, Texas; chairman Scientific Exhibit Committee, Dr Clark W Finnerud, Chicago; executive committee: Dr C Guy Lane, Boston, Dr Jeffrey C Michael, Houston, Texas, and Dr Harry R. Foerster, Milwaukee.

Dr M F Engman Jr, St Louis, read a paper on "Congenital Atrophy of the Skin with Reticular Pigmentation." Discussed by Drs H A Dixon, Toronto, S William Becker, Chicago, Harold N Cole, Cleveland, Fred D Weidman, Philadelphia, Charles F Pabst, Brooklyn, and M F Engman Jr, St Louis.

Dr Joseph V Klauder, Philadelphia, read a paper on "Fever Therapy of Mycosis Fungoides." Discussed by Drs W R Jaffrey, Hamilton, Ont., Paul A O'Leary, Rochester, Minn., Edward F Corson, Philadelphia, C Guy Lane, Boston, and Joseph V Klauder, Philadelphia.

Drs J L Pipkin and C F Lehmann, San Antonio, Texas, presented a paper on "Coccidioidal Granuloma. Report of Two Cases of a Chronic Hypertrophic Type." Discussed by Drs Charles C Tomlinson, Omaha, Howard Morrow, San Francisco, Fred D Weidman, Philadelphia, Donald M Pillsbury, Philadelphia, Joseph Gardner Hopkins, New York, and J L Pipkin, San Antonio, Texas.

Dr Norman M Wrong, Toronto, read a paper on "Hodgkin's Disease of the Scalp." Discussed by Dr Richard W Fowlkes, Richmond, Va.

Drs George C Andrews and Carl B Braestrup, New York, presented a paper on "Depth Dose Measurements for Dermatologic Roentgen Therapy." Discussed by Drs Anthony C Cipolario, New York, and Carl B Braestrup, New York.

Drs M H Goodman and Lloyd W Ketron, Baltimore, presented a paper on "Granuloma Annulare. Report of Unusual Cases, with Remarks on the Histology of This Condition." Discussed by Drs G S Williamson, Ottawa, Ont., Arthur W. Stillians, Chicago, Jeffrey C Michael, Houston, Texas, and Lloyd W Ketron, Baltimore.

Drs Walter O Teichman and Frank J Eichenlaub, Washington, D C., presented a paper on "The Relation of the Endocrine System to Dermatology." Discussed by Drs Barney Usher, Montreal, Hermann Feit, New York, and Frank J Eichenlaub, Washington, D C.

Dr Harold N Cole, Cleveland, moved and Dr Howard Morrow, San Francisco, seconded the motion, that it be the sense of the section that the motion passed at a previous meeting in regard to participants remaining throughout the session be strictly enforced in the future. As to the means of enforcement, it was suggested by Dr Eichenlaub that if a man did not remain through the session he be not invited to participate in the program again. Dr Cole's motion was seconded and carried.

The chairman, Dr Michael, expressed to the Canadian delegates the appreciation of the section for their part in making the meeting successful.

The chairman expressed the appreciation of the section for the work of Dr Fred D Weidman as chairman of the Committee on Scientific Exhibit.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9 15 by the chairman, Dr Robert H Riley, Baltimore.

The chairman appointed the following as the nominating committee: Dr A J Chesley, St. Paul, Dr J N Baker, Montgomery, Ala., and Dr A J Lanza, New York.

On motion of Dr John Sundwall, Ann Arbor, Mich., seconded by Dr W W Peter, Albuquerque, N M., it was voted to nominate Dr Victor G Heiser, New York, and Dr Stuart Fordyce Kitchen, Tallahassee, Fla., for Associate Fellowship.

Dr Robert H Riley, Baltimore, read the chairman's address.

Dr A Grant Fleming, Montreal, in the absence of Dr W J P MacMillan, Charlottetown, P E. I., read the Canadian chairman's address.

Dr Albert S Gray, Hartford, Conn., read a paper on "Importance of Industrial Hygiene and How It Can Best Be Handled by State Departments of Health." Discussed by Drs C O Sappington, Chicago, R. R. Sayers, Washington, D C., Huntington Williams, Baltimore, L D Bristol, New York, and Albert S Gray, Hartford, Conn.

Dr Fred J Wampler, Richmond, Va., read a paper on "Some Observations on a Physical Survey of 47,000 CWA Employees in the State of Virginia." Discussed by Drs L D Bristol, New York, I C Riggins, Richmond, Va., John Sundwall, Ann Arbor, Mich., W W Peter, Albuquerque, N M., Oscar O Miller, Louisville, Ky., Fred J Wampler, Richmond, Va., and R R Sayers, Washington, D C.

THURSDAY, JUNE 13—MORNING

Dr N E McKinnon, Downsview, Ont., read a paper on "The Reduction of Diphtheria in Children Immunized with Toxoid." Discussed by Drs M P Ravenel, Columbia, Mo.,

D T Fraser, Toronto, J N Baker, Montgomery, Ala., and N E McKinnon, Downsview, Ont.

Dr James G Cumming, Washington, D C., read a paper on "Tuberculosis The Interval of Supervisory Treatment and Prophylactic Control" Discussed by Dr S Adolphus Knopf, New York

Dr John L Rice, New York, read a paper on "Health Problems in New York City"

Dr S E Gould, Eloise, Mich., read a paper on "Age Distribution and Longevity of the Syphilitic."

Dr Julius Levy, Newark, N J., read a paper on "Child Health Survey of Preschool Children, Conducted as CWA Project." Discussed by Dr LeRoy A Wilkes, Trenton, N J

Drs Clarence L Hyde and Carl R Steinke, Akron, Ohio, presented a paper on "The Importance of the Closure of Pulmonary Cavities in the Prevention of Tuberculosis"

Dr W T B Mitchell, Montreal read a paper on "Mental Hygiene in Its Relationship to Public Health and Preventive Medicine"

Louis I Dublin, New York, read a paper on "Trends of Cancer Incidence, Mortality and Curability"

Dr A J Lanza, New York, read a paper on "Asbestosis"

Dr R Vance Ward, Montreal, read a paper on "Tuberculosis in Industry"

FRIDAY, JUNE 14—MORNING

Drs Howard B Sprague and Paul D White Boston presented a paper on "The Etiology of Heart Disease, with Special Reference to the Present Status of the Prevention of Heart Disease."

Dr George E Fahr, Minneapolis, read a paper on "The Heart in Hypertension"

Dr Alfred C Cohn, New York, read a paper on "An Analysis of the Apparent Increase in Heart Disease"

Dr William D Stroud, Philadelphia, read a paper on "The Rehabilitation and Placement in Industry of Those Handicapped with Cardiovascular Disease"

Dr O F Hedley, Philadelphia, read a paper on "A Critical Analysis of Heart Disease Mortality"

These five papers were discussed by Drs Haven Emerson, New York, Harold E. B Pardee, New York Timothy Leary, Boston, S Adolphus Knopf, New York, Samuel Friedman New York, Harold B Wood, Harrisburg, Pa Howard B Sprague, Boston, George E Fahr, Minneapolis, and O F Hedley, Philadelphia

The following officers were elected chairman, Dr R R Sayers, Washington, D C., vice chairman, Dr J Lynn Mahaffey, Trenton, N J., secretary, Dr Henry Hanson, Jacksonville, Fla., delegate, Dr Stanley H Osborn Hartford, Conn Executive Committee, Dr Wilson G Smilie, Boston, Dr Robert H Riley, Baltimore, and Dr R. R. Sayers, Washington, D C

SECTION ON UROLOGY

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9 15 by the chairman, Dr Stanley R Woodruff, Jersey City, N J

The following papers were read as a symposium on "Genito-Urinary Anomalies and Their Treatment"

Dr Robert Gutierrez, New York "The Role of Anomalies of the Kidney and Ureter in the Causation of Surgical Conditions"

Dr Allen B Hawthorne, Montreal "The Embryologic and Clinical Aspects of Double Ureter"

Dr Gilbert J Thomas, Minneapolis "The Ectopic Pelvic Kidney"

Dr Meredith F Campbell, New York "The Surgical Treatment of Anomalies of the Upper Urinary Tract in Children"

These four papers were discussed by Drs Vincent J O'Connor, Chicago, William P Herbst, Washington, D C., Moses Swick, New York, Louis H Segar Indianapolis Reed M Nesbit, Ann Arbor, Mich., C H deT Shivers Atlantic City, N J., George R Livermore, Memphis Tenn John K. Ormond, Detroit, Robert Gutierrez New York, Allen B Hawthorne, Montreal, Gilbert J Thomas, Minneapolis, and Meredith F Campbell, New York

Drs Charles M McKenna and E E Ewert Chicago presented a paper on "The Operative Treatment for Undescended Testicle." Discussed by Drs R H Jenkins New Haven, Conn., A I Dodson, Richmond, Va H W E Walther, New Orleans and Charles M McKenna, Chicago

Dr William E Stevens, San Francisco, read a paper on "Congenital Obstructions of the Female Urethra" Discussed by Dr Francis P Twinem, New York

Dr Frank S Patch, Montreal read a paper on "Cystitis Cystica" Discussed by Drs Monroe E Greenberger New York George H Ewell, Madison, Wis., and Frank S Patch, Montreal

Dr Clyde W Collings, New York, presented a new instrument for transurethral surgery

THURSDAY, JUNE 13—MORNING

Drs David W MacKenzie, Montreal, and Stanley R. Woodruff, Jersey City, N J presided as co-chairmen

Dr David W MacKenzie, Montreal, read the Canadian chairman's address, entitled "Experimental Studies of Lymphatic Absorption from the Pelvic Organs, with Special Reference to the Question of Renal Infections"

Drs Lloyd G Lewis and Orthello R Langworthy, Baltimore, presented a paper on "New Methods of Diagnosis in Neurogenic Lesions of the Bladder and Vesical Neck" Discussed by Drs John Duff New York, Maurice Muschat Philadelphia, Irving Simons New York, William Bisher, New York, and Lloyd G Lewis Baltimore

On motion made by Dr George R. Livermore, Memphis, Tenn., and regularly seconded and carried, the section went into executive session during the reading of the following three papers

Drs James F McCahey, Lorenz P Hansen and David Soloway, Philadelphia "The Anterior Pituitary-Testis Endocrine Relation in the Human Being"

Dr William E Lower, Cleveland "A Preliminary Clinical Report on the Treatment of Benign Prostatic Hypertrophy by Nonoperative Methods"

These two papers were discussed by Drs William J Ezickson, Philadelphia Richard Chute Boston R J A McComb Toronto, R H Jenkins New Haven, Conn. V D Lespinasse, Chicago D Roy McCullagh, Cleveland James F McCahey, Philadelphia, and William E. Lower, Cleveland.

Dr O S Lowsley, New York "Experimental Studies on Impotence in Man" Discussed by Dr A L Wolbarst, New York.

Drs S W Moore and Roy B Henline, New York, presented a paper on "Experimental Study in Renal Arteriography"

Dr Dorrin F Rudnick, Chicago read a paper on "A Study of the Changes in the Trigon Following Resection"

These two papers were discussed by Drs A J Scholl, Los Angeles and R W Barnes, Los Angeles

Dr John B Lowmes Philadelphia read a paper on "The Indication for Nephropexy, with an Analysis of Results" Discussed by Dr Joseph A Hyams, New York

The chairman appointed Drs Russell S Ferguson New York, and Vincent J O'Connor, Chicago, temporary members of the executive committee in the absence of Drs N G Alcock, Iowa City, and Harry Culver, Chicago

FRIDAY, JUNE 14—MORNING

The following officers were elected chairman Dr J H Morrissey, New York vice chairman, Dr C H deT Shivers, Atlantic City, N J., secretary, Dr W P Herbst, Washington, D C, delegate, Dr H C Bumpus Jr Pasadena, Calif alternate, Dr John B Lowmes, Philadelphia

Dr Stanley R Woodruff, Jersey City N J., read the chairman's address, entitled "Tumors of the Ureter A Consideration of the Various Types Primary and Secondary, with a Report of Two Cases of True Metastases" Discussed by Dr Howard S Jeck, New York A. E. Bothe Philadelphia F C Herrick, Cleveland and Stanley R. Woodruff, Jersey City, N J

Dr William F Braasch Rochester Minn., read a paper on "The Prognosis with Renal Neoplasm and Clinical Data Affecting It" Discussed by Dr H W E Walther, New Orleans Wilham C Quinby Boston Edwin Beer, New York, and William F Braasch, Rochester, Minn

Dr Robin Pearse, Toronto, read a paper on "Choice of Treatment in Carcinoma of the Bladder"

Dr Russell S Ferguson, New York, read a paper on 'Etiology and Pathogenesis of Multiple Tumors of the Genito-Urinary Tract'

These two papers were discussed by Drs N F Ockerblad, Kansas City, Mo, I G Harrison, Philadelphia, A E Bothe, Philadelphia, George E Pfahler, Philadelphia, and Victor D Washburn, Wilmington, Del

Dr Reed M Nesbit, Ann Arbor, Mich, read a paper on 'Total Cystectomy and Urethral Transplantations in Malignant Conditions of the Bladder, with a Description of a New Operative Procedure' Discussed by Drs Edwin Beer New York, Jerome M Lynch, New York C C Higgins, Cleveland Harry O Lepsky, Cincinnati, and William C Quinby, Boston

Dr Ralph M LeComte, Washington D C, read a paper on "The Management of Tumors of the Kidney, Including Cysts and Polycystic Disease."

Dr Ernest M Watson, Buffalo, read a paper on "Carcinoma of the Female Urethra"

Dr Archie L Dean Jr, New York, read a paper on "Teratoid Tumors of the Testes"

These three papers were discussed by Drs Lawrence R Wharton, Baltimore, Henry Singree Philadelphia, George C Prather, Boston, Benjamin S Barringer, New York, Ralph M LeComte, Washington, D C., and Ernest M Watson, Buffalo

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, JUNE 12—MORNING

The meeting was called to order at 9 10 by the chairman, Dr Robert D Schrock Omaha

The chairman introduced Dr R I Harris, Toronto, who presided jointly

Dr G E Haggart, Boston, read a paper on "Comminuted Colles' Fracture in Elderly Patients Method of Treatment and the End Results in Thirty Cases" Discussed by Drs William B Owen, Louisville, Ky Willis C Campbell Memphis Tenn, Robert H Kennedy, New York, and Roland Hammond, Providence, R I

Drs Walter G Stern and Louis E Papurt Cleveland presented a paper on 'Healing of the Newer Bumper Fractures of the Tibia' Discussed by Drs W E Gallic, Toronto, Paul B Magnuson, Chicago, and H Earle Conwell Fairfield, Ala

Drs John C. Wilson and Pierre J Walker Los Angeles, presented a paper on 'Acute Anterior Poliomyelitis A Study of the 1934 Epidemic in Southern California' Discussed by Drs William H Park, New York, Philip Lewin, Chicago J P Leake, Washington, D C., Maurice Brodie, New York, and John C Wilson, Los Angeles

Dr Henry W Meyerding Rochester Minn, read a paper on "Dupuytren's Contracture." Discussed by Drs Sumner L Koch, Chicago, G O Eaton, Baltimore, and A Bruce Gill, Philadelphia

Dr Armitage Whitman, New York, read a paper on 'The Treatment of Scoliosis End Results in the Study of One Hundred Postoperative Cases' Discussed by Drs A B Ferguson, New York and Mathier Cleveland New York

Dr Clarence H Heyman Cleveland read a paper on 'Late Results of Treatment of Congenital Dislocation of the Hip' Discussed by Drs A Bruce Gill Philadelphia, Samuel Kleinberg, New York Joseph A Freiberg, Cincinnati, and Paul C Colonna, New York

THURSDAY, JUNE 13—MORNING

Dr J M Murray Ottawa, Ont, read a paper on 'Traumatic Flail Elbow' Discussed by Drs Edwin W Ryerson, Chicago, G I Bauman, Cleveland, and J M Murray, Ottawa, Ont

Dr George W Armstrong, Ottawa, Ont read a paper on 'Acute Septic Arthritis' Discussed by Drs Robert W Johnson Jr, Baltimore, G A Ramsay, London Ont, Mr Harry Clarke, Royal Infirmary, Manchester, England, R I Harris, Toronto, Willis C Campbell, Memphis, Tenn, Frank R Ober, Boston, and George W Armstrong, Ottawa, Ont

Dr R I Harris, Toronto, read the Canadian chairman's address, entitled 'Fat Embolism A Dangerous Complication of Orthopedic Operations'

Dr Fremont A Chandler, Chicago, secretary, discussed the formation of the Board of Orthopedic Surgery

Dr E. C Janes, Hamilton, Ont, read a paper on "Experiences in Leg Lengthening" Discussed by Drs Paul N Jepson, Philadelphia, James A Dickson, Cleveland, Paul B Magnuson, Chicago, George Anopol, New York, and E C Janes, Hamilton, Ont

Dr D W Gordon Murray, Toronto, read a paper on "Fractures of the Carpal Scaphoid" Discussed by Dr Clay Ray Murray, New York

Dr Fraser B Gurd, Montreal, read a paper on "Post-Traumatic Acute Bone Atrophy A Clinical Entity" Discussed by Drs E W Ryerson, Chicago, Robert V Funsten, University, Va, Ralph G Carothers, Cincinnati, Philip Lewin, Chicago, and Fraser B Gurd, Montreal

FRIDAY, JUNE 14—MORNING

The following officers were elected chairman, Dr Arthur T Legg, Boston, vice chairman, Dr Fremont A Chandler, Chicago secretary, Dr Robert V Funsten, University, Va, delegate, Henry W Meyerding, Rochester, Minn, executive committee Drs James S Speed, Memphis, Tenn, Robert D Schrock, Omaha, and Arthur T Legg, Boston

Dr Henry W Meyerding, Rochester, Minn, presented the report of the delegate to the House of Delegates

Dr Earl D McBride, Oklahoma City, read a paper on "The Conservative Operation for Bunions End Results and Refinements of Technic" Discussed by Drs Paul W Lapidus, New York, and Earl D McBride, Oklahoma City

Dr Willis C Campbell, Memphis, Tenn, read a paper on "An Analysis of Living Cases of Primary Malignant Bone Tumors" Discussed by Drs Henry W Meyerding, Rochester, Minn Bradley L Coley, New York, and Dr Willis C. Campbell, Memphis, Tenn

Dr R I Harris Toronto, extended the thanks of the members of the Canadian Medical Association for the kind and courteous treatment they had received and invited the section and the American Medical Association to meet in Toronto in 1940, when the Canadian Medical Association is meeting jointly with the British Medical Association

Dr Robert D Schrock, Omaha, read the chairman's address, entitled 'Difficulties of Diagnosis of Bone Tumors'

Dr William T Green, Boston, read a paper on "Osteomyelitis in Infancy" Discussed by Drs Frank R Ober, Boston, H Winnett Orr, Lincoln, Neb, and William T Green, Boston

Dr Edward L Compere, Chicago, read a paper on 'Growth Arrest in the Long Bones as a Result of Fractures That Include the Epiphysis'

Dr R A Y Johnston, London, Ont, read a paper on "The Effect of Inflammation on Epiphysis and Slipped Epiphyses"

These two papers were discussed by Drs F C Kidner, Detroit, J Dewey Bisgard, Omaha, Dr Edward L Compere, Chicago, and Dr R A Y Johnston, London, Ont

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr Walter A Fansler, Minneapolis

Drs N B Taylor and C B Weld, Toronto, presented a paper on 'Intestinal Obstruction An Experimental Study' Discussed by Drs A C Ivy, Chicago, and C B Weld, Toronto

Dr N B Dreyer, Halifax, N S, read a paper on "Some Effects of Barbituric Acid Derivatives on Gastro-Intestinal Motility and Absorption in the Cat" Discussed by Drs J A Barga, Rochester, Minn, W J Quigley, Cleveland, and N B Dreyer, Halifax, N S

Drs Martin G Vorhaus, Robert R Williams and Robert E Waterman, New York, presented a paper on "Studies on Crystalline Vitamin B₁ Experimental and Clinical Observations" Discussed by Drs Frederick F Tisdale, Toronto, and Martin G Vorhaus, New York City

Dr Russell L Haden Cleveland, read a paper on 'Multiple Nutritional Deficiency Disease' Discussed by Drs R F

Farquaharson, Toronto, Michael G Wohl, Philadelphia, and Russell L Haden, Cleveland

Drs Burrill B Crohn and Bernard D Rosenak, New York, presented a paper on "Combined Forms of Ileitis and Colitis" Discussed by Drs A A Berg New York Joseph Felsen, Mount Vernon, N Y, Anthony Bassler, New York, and Burrill B Crohn, New York

Drs Lathan A Crandall, George M Roberts and Lowell D Snorf, Chicago, presented a paper on "The Use of Chondroitin in Idiopathic Headache" Discussed by Drs August A Thomen, New York, A F R Andresen, Brooklyn, and Lathan A Crandall, Chicago

Dr Walter A Bastedo, New York, read a paper on "The Value of Belladonna in Stomach Disorders A Summary of Laboratory and Clinical Observations" Discussed by Drs Bruce C Lockwood, Detroit, and Walter A Bastedo, New York.

THURSDAY, JUNE 13—AFTERNOON

Dr Walter A Fansler, Minneapolis read the chairman's address, entitled "The Diagnosis and Prognosis of Epithelial Tumors of the Large Bowel"

Dr R H M Hardisty, Montreal, read the Canadian chairman's address

Dr Curtice Rosser, Dallas, Texas, read a paper on "Diagnostic Criteria of Colonic Cancer" Discussed by Drs Neil John Maclean, Winnipeg, Manit, Sara M Jordan, Boston, Julius Friedenwald, Baltimore, and Curtice Rosser, Dallas, Texas

Dr Neil John Maclean, Winnipeg Manit, read a paper on "Endometriosis of the Large Bowel" Discussed by Drs James D Schofield, Philadelphia, and Neil John Maclean, Winnipeg, Manit

Drs E L Walsh, G H Laing H L Sippy and A C Ivy Chicago, presented a paper on "Behavior of the Average Human Colon" Discussed by Drs Malcolm J Wilson Toronto, N B Dreyer Halifax N S, and A C Ivy Chicago

Dr Philip W Brown, Rochester Minn, read a paper on "Clinical Experience of the Mayo Clinic in the Treatment of Amebiasis" Discussed by Drs Moses Paulson, Baltimore, Sidney K. Simon, New Orleans, and Philip W Brown, Rochester Minn

Drs Herbert T Hayes, Harry B Burr and J Wade Harris, Houston, Texas presented a paper on "Lymphogranuloma Inguinale" Discussed by Drs William H Daniel, Los Angeles, and Harry B Burr, Houston, Texas

Dr Frank C Yeomans New York, read a paper on "Proctologic Conditions in Children" Discussed by Drs Descum C McKenney, Buffalo, and Frank C Yeomans, New York

Dr F B Bowman, Hamilton Ont, read a paper on "Villous Papilloma of the Rectum" Discussed by Drs Edward G Martin, Detroit, and F B Bowman, Hamilton, Ont

FRIDAY, JUNE 14—AFTERNOON

The following officers were elected chairman, Dr Ernest H Gauthier, Baltimore, vice chairman, Dr Louis A. Buie, Rochester, Minn, secretary, Dr A H Aaron, Buffalo, delegate, Dr Curtice Rosser, Dallas, Texas, Executive Committee, Dr A F R Andresen, Brooklyn, Dr Walter A Fansler Minneapolis, and Dr Ernest H Gauthier, Baltimore

Dr Martin E. Refuss, Philadelphia, read the report of the Committee on Dietary Faddism On motion made by Dr Walter A. Fansler, Minneapolis, seconded by Dr Anthony Bassler, New York, the following resolution was adopted

Resolved That the Committee on Dietary Faddism be given the power to combat actively dietary faddism food cults and dietary misinformation by every means in its power subject to the discretion of the Board of Trustees of the American Medical Association

Dr A F R. Andresen, Brooklyn presented the report of the committee appointed to join with a similar committee of the American Gastro-Enterological Association in the formation of an American Board of Gastroenterology On motion made by Dr Henry A Rafsky, New York, seconded by Dr Sara M. Jordan Boston, the report was accepted and approved

Dr Malcolm J Wilson, Toronto, read a paper on "The Function of the Pyloric Sphincter" Discussed by Drs J Earl Thomas, Philadelphia, and Malcolm J Wilson, Toronto

Drs Charles M Wilhelmj and Frederick C. Hill, Omaha presented a paper on "The Regulation of Gastric Acidity"

Discussed by Drs F W Rolph, Toronto, Frank Gorham, St. Louis, and Frederick C Hill Omaha

Drs Samuel J Fogelson and Richmond K. Anderson, Chicago, presented a paper on "The Secretion of Gastric Mucin in Man A Comparative Study in the Normal Subject and Peptic Ulcer Patient in Response to an Alcohol Test Meal" Discussed by Drs B P Babkin, Montreal, and Samuel J Fogelson, Chicago

Drs John Euman and Walter G Karr, Philadelphia, presented a paper on "Relation of Nonprotein Nitrogen Retention to Dehydration and Hypochloremia." Discussed by Drs Simon L Ruskin, New York, Henry A Rafsky, New York Michael G Wohl, Philadelphia, and Walter G Karr, Philadelphia

Dr B P Babkin, Montreal, read a paper on "Blood Sugar Concentration and the External Secretion of the Pancreatic Gland" Discussed by Drs A H Aaron, Buffalo, and B P Babkin, Montreal

Dr Joseph T Beardwood Jr, Philadelphia, read a paper on "Abdominal Symptomatology of Diabetic Acidosis"

Drs Robert W Mathews and Truman G Schnabel, Philadelphia, presented a paper on "Esophageal Carcinoma, with Especial Reference to a Nonstenosing Variety" Discussed by Drs Gabriel Tucker, Philadelphia, and Truman G Schnabel, Philadelphia

Drs James F Weir and Albert M Snell, Rochester, Minn, presented a paper on "Some Sequelae of Cholecystectomy" Discussed by Drs Colin G Sutherland, Montreal, and Henry A Rafsky New York

SECTION ON RADIOLOGY

WEDNESDAY, JUNE 12—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr John W Pierson, Baltimore

The chairman introduced Dr W A Jones, Kingston, Ont., the Canadian chairman, who assumed the chair

Dr W A Jones, Kingston, Ont, read the Canadian chairman's address, entitled "The Role of Anatomy in the Radiologic Study of the Spine"

Dr Albert Soland Los Angeles, presented his report on the resolutions adopted by the section last year, which were presented to the House of Delegates, and Dr C S Gorsline, Battle Creek, Mich, discussed the matter briefly

Drs B R Kirklin and T W Blake, Rochester, Minn, presented a paper on 'A Comparison of the Clinical and Cholecystographic Manifestations of Cholelithiasis' Discussed by Dr I S Ravdin, Philadelphia

Dr A C Singleton, Toronto, read a paper on "Radiologic Observations in Prepyloric Lesions" Discussed by Dr Lewis Gregory Cole, New York

Dr Sherwood Moore, St. Louis, read a paper on "Metabolic Cranioptathy A Clinical Syndrome with Radiographic Lesions in the Cranial Bones" Discussed by Drs Bede J M Harrison Vancouver, B C, M C Sosman, Boston, and E H Skinner, Kansas City, Mo

Drs Karl Kornblum and Philip J Hodes, Philadelphia, presented a paper on "The Roentgenologic Aspects of Osteomyelitis of the Skull" Discussed by Dr E. L Rypins, Iowa City

Dr E H Shannon, Toronto, read a paper on "Observations on the Radiographic Examination of the Accessory Nasal Sinuses" Discussed by Dr Frederick M Law New York

THURSDAY, JUNE 13—AFTERNOON

Dr John W Pierson, Baltimore, read the chairman's address, entitled "Some Roentgenologic Studies in the Dynamics of the Thorax"

Dr John T Farrell Jr, Philadelphia, presented a paper on "Importance of Early Diagnosis in Bronchiectasis A Clinical and Roentgenographic Study of One Hundred Cases" No discussion.

Dr Robert E Cumming, Detroit, read a paper on "Intravenous and Retrograde Urography A Comparative Study" Discussed by Drs Moses Swick, New York, and Robert E Cumming, Detroit

Dr A. H Pirie, Montreal, read a paper on "Clinical Applications of the Method for Reading with Closed Eyes" Discussed by Drs Robert B Taft, Charleston, S C., George W Grier, Pittsburgh, and A H Pirie, Montreal

Drs Max Ritvo Patrick F Butler and Eugene E O Neil, Boston, presented a paper on "X-Ray Diagnosis of Tumors of the Breast" Discussed by Drs L A Pomeroy, Cleveland, John J Gilbride, Philadelphia, and Max Ritvo Boston

Dr E L Shepley, Saskatoon, Sask read a paper on "Cancer An Adequate Offensive Attack" Discussed by Drs Francis Carter Wood, New York

FRIDAY, JUNE 14—AFTERNOON

The following officers were elected chairman Dr Edward Jenkinson, Chicago, vice chairman Dr Ross Golden New York, secretary, Dr John T Murphy, Toledo, Ohio executive committee, Dr A U Desjardins, Rochester, Minn, Dr John W Pierson, Baltimore, and Dr Edward Jenkinson, Chicago

Drs Howard P Doub and Frank W Hartman, Detroit, presented a paper on "X-Rays in Diagnosis and Treatment of Mycogenous Neoplasms" No discussion

Dr Bede J M Harrison Vancouver B C, read a paper on "A New Method of Orientation Applicable to the Body and the Roentgen-Ray Beam" Discussed by Drs W E Chamberlain, Philadelphia, A H Pirie Montreal, and Bede J M Harrison, Vancouver B C

Dr Benjamin S Barringer, New York, read a paper on "Inguinal Gland Metastases in Carcinoma of the Penis" Discussed by Drs George L Pfahler, Philadelphia, and Benjamin S Barringer, New York

Dr U V Portmann Cleveland read a paper on "Roentgen Therapy for Mediastinal Tuberculous Lymphadenitis" Discussed by Drs John S Derr Frederick Md William Snow, New York and U V Portmann Cleveland

Dr M C Morrison, London, Ont, read a paper on "Hodgkin's Disease of Bone" Discussed by Drs W H McGuffin, Calgary, Alta A H Pirie Montreal, W E Chamberlain, Philadelphia U V Portmann, Cleveland M J Tobias, New York Gordon Richards Toronto George E Pfahler, Philadelphia, and M C Morrison London Ont

Drs G Allen Robinson and R Franklin Carter, New York, presented a paper on "Differential Diagnosis and Treatment of Tumors in Children" Discussed by Drs Ralph S Bromer, Bryn Mawr Pa George W Grier, Pittsburgh Eugene P Pendergrass, Philadelphia George L Pfahler Philadelphia, and A H Pirie, Montreal

SECTION ON MISCELLANEOUS TOPICS

Session on Anesthesia

WEDNESDAY JUNE 12—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr John S Lundy Rochester, Minn., who expressed pleasure at the opportunity of welcoming the Canadian Association members and introduced the chairman of the Canadian section Dr Wesley Bourne of Montreal, who took the chair and presided.

Sir Francis E Shipway London England read a paper on "Tribrom-Ethanol An Analysis of 1600 Administrations" Discussed by Drs Albert H Miller, Providence, R I, Walter L Muir Halifax, N S Russell F Sheldon, Boston, C N Chipman, Washington, D C and Sir Francis E Shipway, London England

Dr Paul M Wood, New York read a paper on "Clinical Use of Cyclopropane and Tribrom-Ethanol" Discussed by Drs Harold R Griffith Montreal Henry S Ruth, Philadelphia, Sir Francis E Shipway, London, England Thomas Drysdale Buchanan New York, Philip D Woodbridge, Boston, and Paul M Wood New York

Drs Simon Dworkin and Bernard B Raginsky, Montreal, presented a paper on "The Effect of Anesthetics, Sedatives and Hypnotics on Conditioned Motor Reflexes" Discussed by Drs Wesley Bourne, Montreal, Howard S Liddell, Ithaca, N Y, and Bernard B Raginsky, Montreal

Dr John S Lundy, Rochester, Minn, read the chairman's address, entitled "The Clinical Use of Anesthetic Agents and Methods," following which he took the chair and presided during the remainder of the session

Dr Lincoln F Sise, Boston read a paper on "Anesthesia for Thyrocardiac Patients" Discussed by Drs Ansel M Caine,

New Orleans, Milton J Raisbeck, New York, S C Wiggins, Newton, Mass., and Lincoln F Sise, Boston

Drs Chester M Kurtz, J H Bennett and H H Shapiro, Madison, Wis., presented a paper on "Electrocardiographic Studies During Surgical Anesthesia" Discussed by Drs E A Rovenstine, New York, Lewis M Hurxthal, Boston, Milton J Raisbeck, New York, and Chester M Kurtz, Madison, Wis

Dr Frank W CoTui, New York, read a paper on "Spinal Anesthesia The Experimental Basis of Some Prevailing Clinical Practices" Discussed by Drs Meyer Saklad, Providence R I Philip D Woodbridge, Boston, and Frank W CoTui, New York

Session on History of Medicine

THURSDAY, JUNE 13—MORNING

The meeting was called to order at 9 15 by the chairman, Dr James B Herrick, Chicago

Chairman Herrick introduced the secretary of the Canadian section, Dr H E MacDermot, Montreal, who represented the Canadian chairman, Dr W W Francis, Montreal, who was unable to attend

Dr Herrick read his introductory remarks

Dr David Riesman, Philadelphia read a paper on "Deceased Diseases" Discussed by Drs James B Herrick Chicago, and Philip G Corliss, Somerton, Ariz

Dr H E MacDermot, Montreal, read a paper by Dr Leo E Pariseau, Montreal, on "Jacques Cartier (A D 1535) and the History of Scurvy" Discussed by Drs Richmond C Holcomb, Highland Park, Pa, and H E MacDermot, Montreal

Dr F L Reichert, San Francisco read a paper on "Anatomy in the Making" Discussed by Dr David Riesman Philadelphia

Dr H E MacDermot read a paper by Dr W B Howell, Montreal, on "Walter Henry, Army Surgeon in the Early Nineteenth Century" Discussed by Dr Jabez H Elliott, Toronto

Dr Roland Hammond, Providence R I, read a paper on "Medicine in the Time of the Crusades"

On motion by Dr Richmond C Holcomb, Highland Park, Pa seconded and carried the loss of Fielding Garrison an outstanding, scholarly, medical historian, was deplored, an international loss

The secretary, Dr Major G Seelig St. Louis read a letter from Dr J Oscar Thompson, of Upper Darby, Pa on a letter-head of the Canton Hospital, Canton, China regarding the celebration on Nov 4 1935, of the centenary of the introduction of modern medicine into China and the founding of Canton Hospital by Dr Peter Parker, a graduate of Yale, and the fiftieth anniversary of Dr Sun Yat-Sen's beginning to study medicine at Canton Hospital

It was moved by Dr Isaac A. Abt, Chicago seconded and carried, that the matter be referred to the secretary, with a request that the House of Delegates of the American Medical Association send felicitations of this joint meeting of the session Dr Abt volunteered to present the matter to the House of Delegates at the afternoon session

Dr O H Leber, New York, made a motion, which was duly seconded and carried, that a petition be sent to the House of Delegates that a session on historical medicine be held every year

Session on Military Medicine

FRIDAY, JUNE 14—MORNING

The meeting was called to order at 9 25 by Dr Holman Taylor, Fort Worth, Texas, secretary of the section, who introduced Dr W H Delaney, Quebec, the Canadian secretary, to preside in the absence of the chairman.

Dr George W Rice, Washington, D C, read a paper on "Peace-Time Medical Department Reserve Training" Discussed by Drs E A Meyerding, St Paul, Ernest Fulton Risdon, Toronto, Holman Taylor, Fort Worth, Texas, and John B Klopp, Chester, Pa

Dr Ernest Fulton Risdon, Toronto, read a paper on "Surgical Care of the Facially Wounded." Discussed by Dr Robert H Ivy, Philadelphia

Dr M C Stayer, Carlisle, Pa, read a paper on "The Relationship of the Medical Officer to the Combat Officer" Discussed by Drs Holman Taylor, Fort Worth, Texas, and James H Huddleson, New York.

Dr P R Bolus, Ottawa, Ont, read a paper on "Shell Shock in Past and Future Wars" Discussed by Drs James H Hudson, New York, and P R. Bolus, Ottawa, Ont

Dr Charles H Frazier, Philadelphia, read a paper on "The Modern Treatment of Surgical Shock" Discussed by Drs Charles C Lund, Boston, and Norman E. Freeman, Boston

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Atlantic City session occupied the largest amount of floor space in the history of the Association, covering more than 45,000 square feet. There were more than 200 exhibits of a purely scientific nature. All fifteen sections of the Scientific Assembly participated through special section exhibit committees appointed for the purpose, while the exhibits were correlated closely with the papers read in the Scientific Assembly.

There were four special exhibits authorized by the Board of Trustees. The exhibit on diabetes, under the direction of a committee headed by Dr E P Joslin of Boston, covered all aspects of diabetes and its treatment. The other members of the committee were F G Banting, co-chairman, Toronto, C H Best, Toronto, H F Root, Boston, R M Wilder, Rochester, Minn, and R T Woodyatt, Chicago. This committee was assisted by a corps of demonstrators, as follows: F M Allen, New York, C J Barborka, Chicago, J T Beardwood, Philadelphia, C F Bolduan, New York, B D Bowen, Buffalo, Gladys L. Boyd, Toronto, W R Campbell, Toronto, C D Christie, Cleveland, L I Dublin, New York, Reginald Fitz, Boston, H R Geyelin, New York, Henry J John, Cleveland, W R Jordan, Richmond, Va, E P Joslin, Boston, C F Kemper, Denver, H L Lombard, Boston, Alexander Marble, Boston, E H Mason, Montreal, H O Mosenthal, New York, J E Paullin Jr, Atlanta, Ga, Elaine Ralli, New York, E L Sevringhaus, Madison, Wis, H J Spencer, New York, T P Sharkey, Dayton, Ohio, Shields Warren, Boston, Priscilla White, Boston, and J W Williams, Rochester, N Y.

The exhibit on the prevention of asphyxial deaths was presented under the direction of a committee headed by C L Jackson, Philadelphia, assisted by a committee composed of Harrison S Martland, Newark, N J, and R R Sayers, Washington, D C. This committee was assisted by a corps of demonstrators, as follows: Alvan L Barach, New York, Charles L Bossert, Atlantic City, N J, C W Buckmaster,

Yonkers, N Y, Jesse G M Bullowa, New York, P J Flagg, New York, Wheaton Fregeau, New York, John F McGrath, New York, A Harry Neffson, New York, Lawrence W Smith, New York, and Warren T Vaughan, Richmond, Va. Each of the three members of the committee had fine exhibits in this group. Special commendation is given to the Atlantic City life guards for the excellent demonstration which they gave in connection with this exhibit.

The exhibit on vaccines and serums was a cooperative undertaking by the Committee on Scientific Exhibit and the United States Public Health Service. The committee in charge consisted of R C. Williams, chairman, Washington, D C., James P Leake, Washington, D C., and W G Workman, Washington, D C., this committee was assisted by the following demonstrators: C F McKhann, Boston, S S Cook, Washington, D C., W T Harrison, Washington, D C., and R H Miller, Washington, D C.

The special exhibit on nutrition was presented by a committee composed of Reginald Fitz, chairman, Boston, Walter C Alvarez, Rochester, Minn., and L H Newburgh, Ann Arbor, Mich.

Among the section exhibits there were several special features. The Section on Dermatology and Syphilology had a special symposium on syphilis, and the Section on Preventive and Industrial Medicine and Public Health had a symposium on tuberculosis. There were so many exhibits on cancer that they were grouped together to form a symposium on cancer. There were several motion picture programs sponsored by sections, including the Section on Orthopedic Surgery, the Section on Obstetrics, Gynecology and Abdominal Surgery, the Section on Nervous and Mental Diseases and the Section on Ophthalmology.

There were 205 exhibits open to awards, including eighteen educational exhibits. The four special exhibits and the awards of the American Medical Association are not open to awards.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report:

CLASS I

[Awards in Class I are made for exhibits of individual investigations, which are judged on the basis of originality and excellence of presentation.]

The gold medal to F L Adair and M Edward Davis, Department of Obstetrics and Gynecology, University of Chicago, Chicago, for original investigations in the development of ergot as a therapeutic agent and especially of a new active principle isolated in crystalline state from ergot, together with its pharmacologic and medicinal properties.

The silver medal to L G Rowntree, J H Clark and Arthur Steimberg, Philadelphia Institute of Medical Research, Philadelphia General Hospital, Philadelphia, and A M Hanson, Faribault, Minn, for original investigations on the biologic effects of thymus and pineal extracts.

The bronze medal to Jane Sands Robb, J G Fred Hiss and R C Robb, Syracuse University School of Medicine, Syracuse, N Y, for original investigations on cardiac muscle-bundle physiology and experimental coronary lesions.

Certificates of Merit, Class I are awarded to the following (alphabetically arranged):

Bede J Harrison, Vancouver General Hospital, Vancouver, B C, for exhibit illustrating a new method of orientation applicable to the body and the x-ray beam.

Aaron E Kanter, Carl P Bauer and Arthur H Klawans, Rush Medical College of the University of Chicago, Chicago, for exhibit illustrating a new biologic test for hormones in pregnancy urine.

Isaac Schour and A G Brodie, University of Illinois College of Dentistry, Chicago, for exhibit illustrating the effect of metabolic disturbances on teeth.

CLASS II

[Awards in Class II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation.]

The gold medal to Stuart Harrington and Willis S Lemon, Mayo Foundation for Medical Education and Research, Rochester, Minn, for excellence of presentation of exhibit illustrating the surgical treatment and clinical manifestations of various types of diaphragmatic hernia and intrathoracic tumors.

The silver medal to David W MacKenzie and Alexander B Wallace, urologic department, Royal Victoria Hospital, Montreal, for excellence of presentation of exhibit on lymphatic studies, particularly relation of lower urinary and genital tracts to renal infections.

The bronze medal to James Harold Mendel, Philadelphia, for excellence of presentation of exhibit on ear drums and their interpretation.

Certificates of merit, Class II, are awarded to the following (alphabetically arranged):

T G H Drake, Hospital for Sick Children, Toronto, for excellence of presentation of exhibit illustrating infant care and feeding in ancient times.

Jacob Gershon-Cohen and Albert Strickler, Philadelphia Skin and Cancer Hospital, Philadelphia, for excellence of presentation of exhibit illustrating roentgenographic studies of the normal female breast.

C C Higgins, Cleveland Clinic, Cleveland, for excellence of presentation of exhibit illustrating transplantation of ureters
Dudley C. Smith, W A Brumfield Jr and E C Barksdale, University of Virginia Charlottesville, Va for excellence of presentation of exhibit illustrating practical epidemiology of syphilis

HONORABLE MENTION

In addition, the following exhibits are deemed worthy of honorable mention (alphabetically arranged)

That of Maude E Abbott, McGill University, Montreal, illustrating the clinical classification of congenital heart disease

That of K. K. Chen, Charles L Rose and G H A Clowes, Lilly Research Laboratories, Indianapolis on cyanide poisoning

That of Theodore Cornbleet and E R. Pace University of Illinois College of Medicine, Chicago, on the physiologic and biologic studies of sweat with clinical implications

That of M S Dooley and J Solon Mordell University Hospital and College of Medicine, Syracuse University, Syracuse, N Y, on rational drug therapy in hospitals

That of Earl W Florsdorf and Stuart Mudd, University of Pennsylvania School of Medicine, Philadelphia on the preservation of serum and other biologicals by desiccation in vacuo from the frozen state

That of Frank W Hartman, R. D McClure and C I Allen, Henry Ford Hospital, Detroit, on the pathology and treatment of burns

That of Sherwood Moore, the Edward Mallinckrodt Institute of Radiology, Washington University School of Medicine St Louis, on a new metabolic disorder and its pathognomonic radiology signs in the skull

That of Norman Treves, Memorial Hospital New York, on inflammatory carcinoma of the female breast

That of S A Weisman, University of Minnesota Medical School, Minneapolis, on the normal development of the human chest.

GROUP EXHIBITS

A special certificate of merit is awarded to each of the following group exhibits

Group exhibit from Temple University School of Medicine, Philadelphia, on the correlation of clinical results obtained in various branches of medicine by regulation of the cerebral hydrodynamics and the methods of treatment involved. The following individuals were responsible for this work Temple Fay, W E Chamberlain, J O Arnold John Royal Moore, J Garrett Hickey, Nicholas Gotten and John H Taefner

Group exhibit from the University of Pennsylvania School of Medicine, Philadelphia on the small intestine. The following individuals were responsible for this work T Grier Miller, W Osler Abbott Katherine OS Elson William G Karr P J Morrison, I S Ravdin, Charles G Johnson Wright Wilson, F A Cajori, Edwin J DeBeer Henry K. Pancoast, Eugene P Pendergrass, Philip J Hodes and J Robert Andrews

Group exhibit from Columbia University and the Hospital for Joint Diseases, New York, aided by Carnegie Institution of Washington, D C, on studies on crystalline vitamin B₁. The following individuals were responsible for this work Robert E Waterman, John C Keresztesy H T Clarke Samuel Gurin, Edwin R. Buchan, A E Ruehle, Oscar Wintersteiner, Martin G Vorhaus, Sidney Berkowitz, and Robert R Williams and Marion Ammerman

Group exhibit from the Lahey Clinic on Surgical Treatment of Thyroid Diseases, exploration of common duct and abdominal perineal resection of the rectum Frank H Lahey and Richard B Cattell were responsible for this work.

EDUCATIONAL CLASSIFICATION

A special certificate of merit is awarded to the American Heart Association, New York for its exhibit illustrating heart disease as a sudden cause of death and cardiac disability associated with thyrotoxicosis

SPECIAL EXHIBITS

The Committee on Awards wishes particularly to commend the special exhibits sponsored by the American Medical Association and feels that a special debt of gratitude is owed to

Dr E P Joslin and his committee for the splendid exhibit on diabetes to Dr C L Jackson and his committee for the splendid exhibit on the prevention of asphyxial death, with a special vote of thanks to the Atlantic City life guards for their demonstrations, to the United States Public Health Service for its cooperation in the exhibit on vaccines and serums, and to Dr Reginald Fitz and his committee for the nutrition exhibit.

SPECIAL COMMENDATIONS

The Committee on Awards desires to commend especially the following exhibits

Those exhibits illustrating the symposium on syphilis by the Section on Dermatology and Syphilology and the symposium on tuberculosis by the Section on Preventive and Industrial Medicine and Public Health

Those of the various councils and bureaus of the American Medical Association

The Committee on Awards wishes to express its appreciation as well as that of the Committee on Scientific Exhibit of the Board of Trustees for the splendid cooperation of the Canadian Medical Association in sending so many outstanding exhibits to this meeting

Special commendation is given to the exhibit on the Dionne quintuplets by Dr Allan Roy Dafoe, Callander, Ont., and Dr William A Dafoe, Toronto

RECOMMENDATIONS

The Committee on Awards wishes to draw attention to the larger number of exhibits this year illustrating experimental investigations of direct clinical interest. The committee realizes fully the fundamental value of accurate observations in medicine and recognizes that the physician in general practice must ever be kept in mind in the presentation of exhibits, yet it wishes to emphasize also that exhibits showing the most recent advances in experimental medical investigations must be encouraged

The Committee on Awards believes that the policy of correlating the Scientific Exhibit with the Scientific Assembly by the appointment of section exhibit committees is advantageous and it is noted with satisfaction that all the sections have again appointed such committees. The attention of the section officers is respectfully directed to the fact, however, that the section exhibit committees must be chosen with great care so that the most noteworthy research in the various specialties may be represented in the Scientific Exhibit. The Committee on Awards suggests that perhaps the time has come when the committees should consider a selective limitation of section exhibits to be included in the Scientific Exhibit in order better to control its size and at the same time secure exhibits of the most important work in the different fields of medicine

The Committee on Awards wishes to commend especially the large number of individual exhibitors who have developed their exhibits entirely from their own resources and without outside financial aid

The Committee on Awards believes that the members and Fellows of the American Medical Association owe a debt of gratitude to the Committee on Scientific Exhibit of the Board of Trustees to the Advisory Committee and to Dr Thomas G Hull executive in charge of the arrangements of the Scientific Exhibit

The Committee on Awards feels that it cannot commend too highly the appropriate arrangements general and special, the excellent management, the instructiveness and the scientific as well as the practical value of the exhibit. Many physicians and investigators, often at great personal sacrifice have presented exhibits dealing with various aspects of medicine, prepared by means of modern methods and devices for the visualization of the most recent advances. The committee also desires to praise the efforts by many exhibitors to increase the attractiveness of their exhibits

LUDVIG HEKTOEN, Chairman, Chicago
D CHESTER BROWN, Danbury, Conn
EBEN J CAREY, Milwaukee
D SCLATER LEWIS, Montreal
THOMAS G ORR, Kansas City, Mo
RALPH M TYSON, Philadelphia

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bill Passed—H 300 has passed the house, proposing to prohibit the sale or distribution of barbital, sulphonethylmethane (trional), sulphonmethane (sulphonol), diethylsulphon diethylmethane (tetronal), paraldehyde and chloral or chloral hydrate and any derivatives, compounds or mixtures of any of these drugs possessing hypnotic properties or effects, except on the written prescription of a licensed physician.

ARKANSAS

Personal—Dr John H Weaver has been appointed health officer of Hope and Dr Andrew S Gregg health officer of Fayetteville.

Society News—Dr Bryce Cummins, Little Rock, among others, addressed the Southeast Arkansas Medical Society recently on control of acute infectious disease with the latest vaccines and serums.—Speakers before the Lawrence County Medical Society at a recent meeting were Drs Horace R. McCarroll, Walnut Ridge, on "Puerperal Eclampsia," and Thomas C Guthrie, Smithville, "Vomiting of Pregnancy."—The Mississippi County Medical Society was addressed recently by Drs Duane M Carr on surgery in diseases of the chest, Conley H Sanford, treatment of pneumonia, and Thomas D Moore, Memphis, Tenn, conservative treatment of surgical lesions of the kidney.—A symposium on diabetes constituted the program of the Garland and Sebastian county medical societies recently. Speakers were Drs Arthur F Hoge, Everett C Moulton and James W Anis, Fort Smith. At a meeting of the Sebastian County Medical Society, May 13, Dr Clarence B Billingsley, Fort Smith discussed enuresis and Dr Ira F Jones, Fort Smith, pyelitis in childhood.

CALIFORNIA

Exhibit of Rare Books—The University of California Medical School Library announces an exhibition of rare books recently presented to the medical school by Mrs Myrtle Crummer Ingram, in memory of her late husband, Dr Leroy Crummer. Included in the collection are the 1651 edition of Harvey's work on generation, a Latin edition of Rosslin's "de Partu Hominis" the Renaissance work on obstetrics, Phrysius's "Spiegel der Artzney", the 1628 edition of Aselli's "De Lactibus" and the famous poem by Alexander Pope "An Epistle to Dr Arbuthnot."

State Association Cooperates with Medical Schools—The house of delegates of the California Medical Association recently decided to sponsor a series of state-wide graduate courses in cooperation with the medical schools of the state. A series of courses was recently concluded in the districts about Santa Rosa, Sacramento, San Jose and Fresno, in collaboration with local groups of practicing physicians under the auspices of the University of California Medical School. The data developed from this series were turned over to the state medical association, which appointed a committee to work out the details of the future meetings and clinics.

Society News—The Los Angeles Society of Neurology and Psychiatry was addressed, June 19, by Dr George Creswell Burns among others, on 'Psychoses Due to Bromide Intoxication'.—Dr Leon J Menville, New Orleans, discussed visualization of the lymphatic system before the radiologic section of the Los Angeles County Medical Association, May 8.—A symposium on tuberculosis was presented before the San Diego County Medical Society, June 11, by Drs Bryant R. Simpson, Rudolph H Sundberg and Einar H Christopherson.—The Los Angeles Surgical Society was addressed, May 10, among others, by Dr James F Percy on "Cautery Excision and Protein Absorption in the Treatment of Accessible Cancer."

Reunion of Past Presidents—At the recent meeting of the California Medical Association, the first annual reunion of past presidents was held at an informal breakfast, May 14. Of the eleven past presidents in attendance at the session nine were present: Drs George H Kress, Los Angeles, 1917, Cornelius Van Zwaluwenburg, Riverside 1919, John H Graves, San Francisco 1922, Edward N Ewer, Oakland, 1926, William H Kiger, Los Angeles, 1927, Morton R Gibbons, San Francisco,

1929, Lyell C Kinney, San Diego, 1930, Junius B Harris, Sacramento, 1931, and George G Reinle, Oakland, 1933. Dr Robert A Peers, Colfax, president-elect, presided. Speakers included Drs James S McLester, Birmingham, then President-Elect, American Medical Association, and Clarence G Toland, Los Angeles, then president of the state association.

CONNECTICUT

Portrait of Dr Winternitz—An oil portrait of Dr Milton C Winternitz, dean, Yale University School of Medicine, was presented to the school by the student body, June 17, at the annual meeting of the Association of Yale Alumni in Medicine in the Sterling Hall of Medicine. Dr Winternitz retires from the deanship this year after fifteen years' service. Dr Stanhope Bayne-Jones, who will succeed Dr Winternitz as dean, accepted the portrait in behalf of the school and university. Charles-Edward A Winslow, Dr P H, was among the speakers. Dr George Blumer, New Haven, was chosen president of the alumni association for the coming year.

Changes in Health Officers—Dr Edward J Finn has been appointed to succeed Dr Francis I Nettleton as health officer of Shelton and Dr John D Milburn to succeed the late Dr Frederick T Fitch as health officer of East Hampton. Dr Thomas O Murry is health officer of Beacon Falls, succeeding Dr David H Bluestone, who now lives in Naugatuck. Dr Charles E. Kaufman West Haven, is completing the unexpired term of the late Dr Charles A Bevan. Dr Matthew Griswold will complete the unexpired term of the late Dr Roger M Griswold as health officer of the town of Berlin. Dr John J Gaffney has been appointed town health officer of Danbury, succeeding Dr Felix F Tomaino, who was recently named health officer of the city of Danbury.

DISTRICT OF COLUMBIA

Medical Bills in Congress—S 2939 has been reported to the Senate, providing for the issuance of a license to practice the healing art in the District of Columbia to Dr Ronald A Cox (S Rept No 940).

GEORGIA

Increase in Rabies—There were 1,104 heads of animals examined for rabies in the laboratory division of the state department of health during 1934, as compared with 951 during 1933. Between 40 and 50 per cent of these examinations showed positive results, it was stated. During the first four months of 1934 a total of 177 heads were found positive and a total of 1,105 human treatments administered while for the same period of 1935 a total of 247 positive heads were found, with a total of 1,226 human treatments.

ILLINOIS

Bill Passed—H 44 has passed the house and senate, proposing to repeal the laws regulating the distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act.

Modification of Quarantine Regulations—The Illinois State Department of Health has announced changes in the quarantine regulations effective at once. Patients with epidemic encephalitis will be isolated for two instead of three weeks and the quarantine period for measles is reduced to five instead of seven days from the date of appearance of the rash, provided the catarrhal symptoms have cleared up. Hospital patients with communicable disease may not be removed or discharged without the consent of the local or state health authorities. Common carriers are forbidden to transport birds of the parrot family without a certificate signed by the state health authority indicating freedom from psittacosis. Quarantine of patients with whooping cough is made more stringent requiring isolation of all patients for three weeks after the onset of the paroxysmal cough. The modified quarantine which permitted these patients, identified by special arm bands the freedom of the home premises, has been rescinded. Scarlet fever patients must always be isolated for a minimum period of three weeks and longer if necessary on account of complications. Release by laboratory tests of specimens has been abandoned as impracticable. Ophthalmia neonatorum must be reported within six hours after detection, according to the new rules.

Chicago

Catalogue of Medical Literature at Crerar Library—The Institute of Medicine of Chicago announces that the union catalogue of medical literature in the city is now open to the medical public for reference. Installed on the twelfth floor of the John Crerar Library the catalogue represents the holdings in the libraries of the colleges of medicine and dentistry of

Northwestern University, of the colleges of medicine, dentistry and pharmacy of the University of Illinois, most of the holdings in the biomedical libraries of the University of Chicago, and much of those in the John Crerar Library and in the library of Rush Medical College. The card index is up to date, the medical libraries each month send in cards for their new acquisitions, it is hoped to include soon the important material in the smaller medical libraries of the city. The initial fund for the establishment of the catalogue was made available two years ago by the Institute of Medicine. The organization work was entrusted to a committee on coordination of medical libraries in Chicago, which had been appointed the previous year. The first aim of the committee was to bring about closer integration of effort among the major medicobiologic libraries of the city, to obviate unnecessary duplication of special literature, and to divert the economies achieved to a fuller representation of the world's medical literature in Chicago. The second aim was the creation of a union card index centrally placed, so that investigators in medical problems may locate reference volumes with the least expenditure of time and energy.

INDIANA

Hospital News—Funds to provide a three story annex to the Ball Memorial Hospital Muncie have been made available by the Ball family, the new addition is expected to cost \$200,000.—St Joseph Hospital, Mishawaka celebrated its twenty fifth anniversary, April 22.

Personal—Dr Benjamin J Teaford, Jonesville has been appointed health commissioner of Bartholomew County.—Dr Dudley A Pfaff, Indianapolis has been named a member of the newly created merit commission for the police and fire departments, according to the Indianapolis Star.

IOWA

Society News—Dr Cora Beale Williams Choate, Marshalltown, was elected president of the Society of Iowa Medical Women at its recent annual meeting.—A special joint meeting of the Butler and Mitchell County medical societies was recently addressed at Greene by Drs George E Krepelka, Stacyville, on 'Resection of the Small Bowel,' and Theodore E Blong, Stacyville 'Diabetes Mellitus.' Dr John O Eiel, Osage, reported a case of pancreatic cyst.—A symposium on gall-bladder diseases was presented before the Cerro Gordo County Medical Society recently by Drs Charles and Joseph G Mayo and Claude F Dixon all of Rochester, Minn.—Speakers before a joint meeting of the Johnson Cedar Muscatine, Louisa, Washington and Iowa county medical societies May 1, in Iowa City, included Drs Arthur C Pattison and Frederic E Hambrecht, on 'The Factor of Age in the Mortality of Acute Appendicitis' and Russell's Traction in Fractures of the Femoral Shaft respectively.—Dr George H Bissett, Sac City, addressed the Sac County Medical Society in Odebolt recently on 'Arteriosclerosis and Hypertension.'

LOUISIANA

Personal—Dr Asahel J Hockett since 1931 chief resident physician at State of Wisconsin General Hospital, Madison, Wis., has been appointed superintendent of the Touro Infirmary, New Orleans, succeeding Dr Basil C MacLean.

Society News—At a meeting of the Orleans Parish Medical Society, June 24, Harold Hinman, Ph D and Dr Rudolph H Kampmeier discussed 'Trichiniasis in Louisiana' and 'Clinical Aspects of Trichiniasis' respectively. Dr Sydney Jacobs spoke on 'Pituitary Infantilism'.—Dr George A Mayer was chosen president of the New Orleans Gynecological and Obstetrical Society at a recent meeting.

MARYLAND

Personal—Drs William Allen Deckert, John M Haws and Isadore A Siegel have been appointed health officers in the division of maternity hygiene of the Baltimore Health Department.

Society News—Dr Wilder Graves Penfield, director, Montreal Neurological Institute among others addressed the Johns Hopkins Medical Society, Baltimore, April 8, on 'Head Pain'.—Dr John A Kolmer, Philadelphia, discussed vaccine used in the prevention of infantile paralysis before the Washington County Medical Society recently, in Hagerstown.

In Memory of Dr Welch—A bronze plaque was unveiled and dedicated at the Happy Hills Convalescent Home for Children, Baltimore, June 5, in honor of the late Dr William H Welch one of the founders and first president of the institution. The tablet was unveiled by Dr Henry Barton Jacobs, also one of the founders and present vice president of

the home. Addresses were made by Dr Edwards A Park and by Mr Alfred Jenkins Shriver, a friend of Dr Welch. The home contains accommodations for sixty children and offers convalescent care without charge to those who are unable to receive proper treatment in their homes. Dr Benjamin Tappan is medical director.

MASSACHUSETTS

Health Service Plan for Employees—The New England Health Center, comprising the Boston Floating Hospital, Boston Dispensary and Tufts College Medical School, has adopted a health service plan by which a standard of health supervision will be maintained for its employees. The plan, which covers routine physical examination, the keeping of records, and treatment, will be under the direction of Dr Katherine S Andrews of the department of medicine.

Personal—Dr Walter B Cannon, George Higginson professor of physiology, Harvard Medical School, Boston, was elected an honorary member of the National Academy of Medicine of Spain at the recent celebration of the two hundredth anniversary of its founding, *Science* reports.—Dr Abraham Myerson was recently appointed clinical professor of psychiatry at Harvard Medical School, Boston.—Dr Charles Sidney Burwell, dean elect and research professor of clinical medicine, Harvard Medical School, Boston, has been appointed to the staff of Peter Bent Brigham Hospital, where he will continue clinical investigations of heart disease.

State Medical Meeting and Election—Dr Charles E Moigan, Somerville, was chosen president of the Massachusetts Medical Society at its recent annual meeting in Boston, June 3-5. Dr Channing Frothingham, Boston, was named vice president, and Dr Alexander S Begg, Boston, secretary. Dr Begg has been acting secretary since the death of Dr Walter L Burrage. The next annual session will be held in Springfield. The Shattuck Lecture was delivered Monday evening by Dr William E Gallic, professor of surgery, University of Toronto Faculty of Medicine, on 'Sprains and Dislocations.' Speakers from outside the state included:

Dr Carl Henry Davis, Milwaukee, 'Diagnosis and Treatment of Lesions of the Cervix Uteri.'
Dr William Bierman, New York, 'Fever and Short Wave Radiations.'
Dr John R Carty, New York, 'Diagnostic Possibilities in Soft Tissue Radiography.'
Dr John P Peters, New Haven, Conn., 'Factors in Etiology of Bright's Disease.'

At this meeting, Dr David Cheever, surgeon at the Peter Bent Brigham Hospital, was designated official press representative of the association, the first time the society has filled this position. The society plans to make a survey next September to determine whether there are adequate medical and hospital facilities in the state.

MICHIGAN

Personal—Dr James L McCartney, director of mental hygiene at Battle Creek Sanitarium, has resigned to become chief psychiatrist at the New York State Vocational Institution on the Hudson River at West Coxsackie, N Y, a correctional institute operated by the state department of correction for boys between the ages of 10 and 16.—Dr Linda Gage Roth, dean of women at Battle Creek College, was elected president of the Michigan Student Health Association at a meeting, May 4.—Wayne University conferred the honorary degree of doctor of science in education on Dr William M Donald, Detroit, at its recent commencement.—Dr Thomas R. Ponton has been named acting superintendent of Hurley Hospital, Flint.

Society News—Dr Henry J Pyle, Grand Rapids, was elected president of the Michigan Association of Industrial Physicians and Surgeons at its recent annual meeting.—Dr Paul S Barker, Ann Arbor, conducted a clinic and talked on 'Heart Disease in Children' before the Barry County Medical Society recently in Hastings.—At a meeting of the Shiawassee County Medical Society in May Drs Lloyd E Verity and Russell L Mustard, Battle Creek, discussed peptic ulcer.—Dr Myron William Clift, Flint, spoke on 'Common Pathologic Changes in the Spine with Especial Reference to the Mechanical Forces Involved' before the St Clair County Medical Society in Port Huron, May 21. Dr George J Curry, Flint, reported a series of six cases of musculospiral palsy.

MISSISSIPPI

Meeting Dedicated to State President-Elect—The Central Medical Society dedicated its meeting in Jackson, June 4 to Dr Harvey F Garrison, Jackson, president-elect of the Mississippi State Medical Association, the first member of the society to be named for this position since 1904. In that year Dr Thomas J Mitchell, Jackson, was elected.

MISSOURI

Class Reunion—A reunion of the class of 1895 of the Missouri Medical College was held, June 15-16 at Wildwood Springs Hotel, Steelville. Dr Robert J Terry, St Louis, acted as toastmaster. Dr Robert E Schlueter, St Louis, gave a history of the class, Dr John Zahorsky, St Louis, read a poem entitled "Forty Years Ago," and Dr Marcellus George Gorin, St Louis, presented reminiscences.

Personal—Dr Ralf Hanks, Fulton, has been named superintendent of state hospital number one at Fulton to succeed Dr Raymond C Fagley, resigned.—Dr Henry J Ulrich has been appointed superintendent of the City Isolation Hospital, St. Louis, succeeding Dr John Eschenbrenner, who resigned, May 1, to enter private practice in Ardmore, Okla. Dr Ulrich has been a resident physician at the hospital since 1929.—Dr Hugh P Muir has been named health commissioner of Columbia to succeed the late Dr Wilford A Norris.

Annual Fall Conference—The thirteenth annual fall clinical conference of the Kansas City Southwest Clinical Society will be held at the President Hotel, Kansas City, October 7-10. A tentative program includes the following physicians:

John Alexander Ann Arbor	Harry S Gradle Chicago
Fred H Albee, New York	Francis E LeJeune New Orleans
William Wayne Babcock Philadel	William S Middleton, Madison
phia	Myrie G Peterman Milwaukee
Harlow Brooks, New York	Edward A Schumann Philadelphia
Arthur C Christie Washington	Albert Soiland Los Angeles
D C	Cyrus C Sturges Ann Arbor
Alfred I Folsom Dallas	

Society News—Dr Oliver C Wenger of the U S Public Health Service, Hot Springs National Park, addressed a meeting of the St Louis Medical Society recently under the auspices of the Missouri Social Hygiene Association. His subject was "Venereal Disease as a Public Health Problem." Speakers before the Society recently were Drs Joseph Edgar Stewart on "Treatment of Fracture of the Neck of the Femur", Arthur M Alden, "Value of Ionization in the Treatment of Certain Forms of Allergy," and Sherwood Moore, "Metabolic Craniopathy".—Dr Jacob Kulowski, St Joseph among others spoke before the Jackson County Medical Society recently on "Osteomyelitis of the Spine and Pelvis."

MONTANA

Society News—At a meeting of the Mount Powell Medical Society at the Montana Hotel, Anaconda May 18 Dr Henry E Michelson, professor of dermatology University of Minnesota Medical School, spoke on "Diagnosis and Treatment of Diseases of the Skin." A clinic was held during the session.

Railway Surgeons' Meeting—The Great Northern Railway Surgeons' Association held its annual meeting in Glacier Park, July 1-2, with the following physicians on the program:

Charles L Scudder Boston Emergency Treatment of Fractures
Loyal Davis Chicago Treatment of Spinal Cord Injuries
Francis J Savage St Paul Fracture of the Surgical Neck of the Humerus
Sumner L S Koch Chicago Treatment of Injuries of the Hand
Archibald E Cardie Minneapolis Management of the Diabetic Railway Employee
Berton J Branton Willmar Minn Malpractice Suits
Leslie J Stauffer Priest River Idaho Alleged Sacro-Iliac Strains
Charles N Spratt, Minneapolis Traumatic Detachment of the Retina
Russell B Richardson Great Falls Dislocations of the Knee Joint
John G Cunningham Spokane Wash Septic Arthritis of the Knee Joint
Arthur N Collins, Duluth Minn Trauma and the Malignant Testis

NEW JERSEY

Society News—Dr Ralph L. Barrett, New York, discussed "Electrosurgical Treatment of Common Cervical Lesions" before the Middlesex County Medical Society recently.—At a meeting of the Morris County Medical Society, May 16 Dr George G Ornstein New York, spoke on "The Clinical Classification of Tuberculosis."

A New Neuropsychiatric Society—The New Jersey Neuropsychiatric Association was recently organized at a meeting at the Academy of Medicine of Northern New Jersey, Newark, with forty-six members. Officers elected were Drs Christopher C Beling Newark, president, Marcus A. Curry, Greystone Park, vice president and Lewis H Loeser, Newark, secretary. The purposes are "to promote the science and practice of neuropsychiatry and to maintain high professional standards in that field."

NEW MEXICO

State Medical Election—Dr Mallory B Culpepper Carlsbad, was chosen president-elect of the New Mexico Medical Society at the annual meeting in Albuquerque, May 24, Dr Leo

B Cohenour, Albuquerque, was reelected secretary and Dr Charles W Gerber Las Cruces, was installed as president. The 1936 meeting will be held in Carlsbad.

NEW YORK

Annual Alumni Meeting—The Medical Alumni Association of Syracuse University held its annual meeting at the University, June 3-4. Clinics, demonstrations and case reports were presented by members of the staffs of University, St Joseph's and Syracuse Memorial hospitals. Following are the guest speakers:

Dr Leon H Cornwall New York Pathogenesis of Multiple Sclerosis
Dr Emmett A Dooly New York Fracture of the Femoral Neck.—the Technic and Evaluation of the Newer Methods of Treatment
Dr Lewis C Ecker, Washington D C, Tuberculous Atelectatic Cirrhosis
Dr Robert S Dinmore Jr Cleveland Practical Aspects of Gall bladder Disease
Dr Harris A Houghton New York The Coefficient of Correlation Between Ambard's Renal Salt Threshold and the Systolic Arterial Pressure

At the annual banquet at the Hotel Syracuse Monday evening, June 3, Dr Harlow Brooks, New York, made an address on "The Contribution of the American Indian to Modern Life."

New York City

Directory of Social Agencies—The forty-first edition of the Directory of Social Agencies in New York has just been issued by the Welfare Council. Previous editions were published by the Charity Organization Society. In the present volume 1377 agencies are listed, of which 169 are national organizations with headquarters in New York. Child welfare receives the greatest emphasis with 386 agencies listed in this field. The handicapped are helped through forty-three agencies, health education is administered through thirty-three.

Hospital News—Dr Sigismund S Goldwater commissioner of hospitals, gave an address at the annual meeting of the Hospital for Joint Diseases recently on "The City's Hospitals in Theory and Practice".—The new Queens General Hospital, Jamaica, L I will be opened between September 1 and Jan 1 1936. It will have a capacity of 600 beds and be operated by the department of hospitals.—Bellevue Hospital reported a daily per capita cost of food for patients, staff and nurses of 27 cents in 1934, expenditures for the year totaled \$2,862,000.

Academy Desires Relics for Museum—For years the New York Academy of Medicine has been building up a museum of the history of medicine. Believing that persons who possess old medical instruments or other objects of historical interest wish to see them carefully preserved and placed on exhibition the curator of the museum asks that such persons write describing briefly objects they care to present. The museum has a number of duplicates which it will gladly exchange for articles that it does not possess. Letters should be addressed to The Curator, Museum of the History of Medicine New York Academy of Medicine, 2 East One Hundred and Third Street, New York.

Diagnostic Service in Parasitology—The increase in tropical diseases and parasitic infestations, brought about by the influx of people from Puerto Rico and other tropical countries, prompted the city department of health to establish diagnostic services in parasitology at several places throughout the city. The new service is intended for patients referred by private physicians and for patients seeking diagnosis. A survey to determine the prevalence of these tropical conditions is the main objective of the service. Stations are now operating at Meinhard Memorial Health Center which serves as a substation for the East Harlem Health Center, the Post-Graduate Hospital and Long Island College Hospital.

Personal—Dr William Seaman Bainbridge was appointed to represent the United States at the eighth International Congress of Military Medicine, Surgery and Pharmacy in Brussels, June 27 to July 3.—Dr Oswald T Avery of the Rockefeller Institute for Medical Research received an honorary degree of doctor of laws from McGill University, May 30.—E H Lewinski-Corwin Ph.D. was made honorary president of the International Hospital Association after he had presented his resignation as secretary at the congress of the association in Rome May 19-26. Mr Sydney Lamb, Liverpool England was appointed secretary.—Dr Morris L Rakieten New Haven Conn., has been appointed assistant professor of bacteriology at Long Island College of Medicine, Brooklyn.

Death of Dean Miller—Adam M Miller M A dean of Long Island College of Medicine, died suddenly of heart disease at his home in Mountain Lakes, N J, May 28. Dean Miller

was a graduate of Princeton University. From 1903 to 1912 he was instructor in the department of histology and embryology at the College of Physicians and Surgeons of Columbia University and from 1912 to 1914 assistant professor of anatomy. In the latter year he went to the Medical College of the Long Island College Hospital as professor of anatomy, retaining that position until his death. He was made associate dean of the medical school in 1920 and dean two years later. He played a leading part in the reorganization of the school into the present Long Island College of Medicine. He was co author of a textbook on embryology.

NORTH DAKOTA

Society News—Dr Trygve Oftedal, Fargo, was elected president of the North Dakota Academy of Ophthalmology and Otolaryngology at its seventeenth annual session in Minot, recently. The guest speaker was Dr Oscar B Nugent, Chicago. He spoke on 'Ulcers of the Cornea and Their Treatment'.

State Medical Election—Dr William A Gerrish, Jamestown, was chosen president-elect of the North Dakota State Medical Association at its annual meeting in Minot May 28. Drs Edwin L Goss, Carrington, and William H Long, Fargo, vice presidents. Dr Archibald D McCannell, Minot, was installed as president and Dr Albert W Skelsey, Fargo, reelected secretary. Next year's meeting will be in Jamestown.

OHIO

Personal—Oscar A Turner, sophomore medical student at Western Reserve University School of Medicine, Cleveland, received the Steiner Prize in Anatomy for 1935 the university announces, for studies of the growth of adenoids and of anatomy of the brain.

Faculty Changes at Western Reserve—The following promotions in the faculty of Western Reserve University School of Medicine, Cleveland, were recently announced:

Dr Harry Goldblatt to be professor of experimental pathology
Edward Muntwyler, Ph.D. associate professor of biochemistry
John P Quigley, Ph.D. associate professor of physiology
Dr Theodore T Zuck, assistant professor of anatomy
Dr Clyde L Cummer, assistant clinical professor of dermatology and syphilology
Dr John W Holloway, assistant clinical professor of surgery
Dr Arthur J Horech, assistant clinical professor of pediatrics
Dr Fred C Oldenburg, assistant clinical professor of medicine

Dr Gaus E. Harmon, associate professor of hygiene and vital statistics, has resigned to become chief of the bureau of epidemiology of the Chicago Board of Health.

Society News—Drs Arthur J Skeel and Scott C Runnels, Cleveland, addressed the Toledo Academy of Medicine, June 7, on 'Postpartum Hemorrhage and Maternal and Fetal Mortality' respectively.—Dr J Isfred Hofbauer, Cincinnati, addressed the Butler County Medical Society recently on 'Newer Aspects of the Diagnosis and Etiology of Uterine Carcinoma'.—Dr Ray W Kissane, Columbus, addressed the Clark County Medical Society Springfield, recently, on 'Traumatic Heart Disease'.—At a meeting of the Morrow County Medical Society recently in Mount Gilead, Drs Sylvester J Goodman and Eugene F McCampbell, Columbus, discussed 'Toxemias of Pregnancy' and 'Newer Developments in Medicine' respectively.—Dr Louis J Karnosh, Cleveland, discussed 'Psychoses of Great Men' June 7 at a meeting of the Montgomery County Medical Society in Dayton.

OKLAHOMA

Personal—Dr William C Wait, McAlester, has been appointed superintendent of the Western Oklahoma Tuberculosis Sanatorium, Clinton.

Society News—Drs Howard E Snyder, Winfield, Kan., and Charles T Moran, Arkansas City, Kan., addressed the Garfield County Medical Society, Enid, May 30 on 'Postoperative Pulmonary Atelectasis' and 'Relationship Between Sinusitis and Chest Complications', respectively.—Dr Julian Feild, Enid, was elected president of the Oklahoma Pediatric Society at the annual meeting in Oklahoma City in May.

Medical Examiners Reorganize—Five new members were recently appointed to the state board of medical examiners. Drs Thomas McElroy, Ponca City, Calvin E Bradley, Tulsa, James D Osborn Jr, Frederick, Galvin L Johnson, Pauls Valley, and William W Osgood, Muskogee. Drs William T Ray, Gould, and Lewis E Emanuel, Chickasha, were reappointed. At a reorganization meeting Dr McElroy was elected president, Dr Bradley vice president, and Dr Osborn secretary of the board.

OREGON

Society News—At the forty-fourth annual meeting of the Southern Oregon Medical Society in Ashland recently, speakers were Drs Karl H Martzloff, Portland, on 'Recognition of Cancer of the Cervix', John D Humber, San Francisco, 'Surgical Treatment of Angina Pectoris', Warren C Hunter, Portland, 'Some Aspects of Coronary Arterial Disease' and John M Blackford, Seattle, 'Medical Treatment and Follow Up of Gallbladder Disease'.—Papers were presented before the Multnomah County Medical Society recently by Drs John H Fitzgibbon and Charles H Manlove, Portland, on 'Treatment of Cardiospasm' and 'Clinical and Pathological Aspects of Venous Thrombosis', respectively.

PENNSYLVANIA

Society News—Dr John F Erdmann, New York, addressed the Lehigh County Medical Society, Allentown, recently, on 'Cholecystitis and Cholangitis'.—Dr Jesse C Arnold, Philadelphia, addressed the Washington County Medical Society, Washington, recently, on 'therapeutic fever'.

Personal—Brig Gen Matthew A Delaney, commandant of Medical Field Service School U S Army, Carlisle Barracks, received the honorary degree of doctor of science at the annual commencement of Dickinson College, Carlisle, June 10.—Dr Royal H McCutcheon, medical director of the state tuberculosis sanatorium at South Mountain, has resigned to engage in private practice at Bethlehem. Dr Charles C Custer, assistant director, was appointed to succeed Dr McCutcheon.

Philadelphia

Outbreak of Typhoid Follows Picnic—Twenty-seven persons who attended a picnic given by the Gross Post of the American Legion Memorial Day have developed typhoid. The New York Times reported June 27. The health department has undertaken to immunize the remainder of the 400 persons who are said to have attended the picnic. The source of the infection as yet has not been determined.

RHODE ISLAND

Society News—The Providence Medical Association met with the New England Pediatric Society in Providence recently. Speakers were Drs Dennett L Richardson, on immunization against measles, Maurice Adelman, purpura as a complication of scarlet fever, and Murray S Danforth, Legg-Calve-Perthes' disease in children from 4 to 8 years old. Dr Francis M Rackemann, Boston, addressed the Providence Medical Association June 3 on 'Recent Advances in the Management of Asthma and Eczema'.

SOUTH CAROLINA

State Medical Election—Dr Robert C Bruce, Greenville, was named president-elect of the South Carolina Medical Association at the annual session in April, and Dr Edgar A Hines, Seneca, was reelected secretary for the twenty-sixth year. Dr Samuel E Harmon, Columbia, assumed the presidency for this year. The next annual session will be at Greenville.

SOUTH DAKOTA

Society News—At the annual meeting of the South Dakota Academy of Ophthalmology and Otolaryngology in Pierre recently, Dr Ray A Kelly, Mitchell, was chosen president, Dr Anders E Johnson, Watertown, vice president, and Dr Howard L Saylor, Huron, secretary.

TEXAS

State Medical Election—Dr Howard R Dudgeon, Waco, was chosen president-elect of the Texas State Medical Association at the annual meeting in Dallas recently. Dr John H Burleson, San Antonio, was installed as president and Dr Holman Taylor, Fort Worth, was reelected secretary. Next year's meeting will be held in Houston.

Special Societies Elect Officers—Dr Thomas B Bass, Abilene, was elected president of the Texas Neurological Society at its annual meeting in Dallas in conjunction with the Texas State Medical Association in May. Dr Ross B Trigg, Fort Worth, was elected president of the Texas Railway Surgeons Association. Dr Harry G Walcott, Dallas, of the Texas Society of Gastro-Enterologists, Dr Truman C Terrell, Fort Worth, of the Texas State Pathological Society, Dr Edward H Schwab, Galveston, of the Texas State Heart Association, Dr Jeffrey C Michael, Houston, of the Texas Dermatological Society, and Dr Caleb O Terrell, Fort Worth, of the Texas Pediatric Society.

VIRGINIA

University News—Dr Harvey B Stone, Baltimore, delivered the William W Root Memorial Lecture of Alpha Omega Alpha at the University of Virginia Department of Medicine, Charlottesville, recently, on "Transplantation of Endocrine Gland Tissue in Mammals"

Officers of Specialty Society—Dr Emory Hill, Richmond, was elected president of the Virginia Society of Otolaryngology and Ophthalmology at its sixteenth annual meeting, in Fredericksburg recently. Other officers are Drs Joseph Minor Holloway, Fredericksburg, vice president, and George G Hankins, Newport News, secretary, reelected. The next meeting will be held in Richmond in May 1936.

Personal—Dr Albert B McCreary, who has been a member of the staff of the health department of Memphis for several years, has been appointed to take charge of a district health unit in Virginia, with headquarters at Eastville.—The physicians of Martinsville and Henry County recently presented a cane to Dr John W Simmons, Martinsville, in honor of his completion of fifty years of medical practice. Dr Simmons has been coroner of Henry County for many years.

WISCONSIN

Bill Passed—A 733 has passed the assembly, proposing to authorize the state medical society of Wisconsin, or any county medical society, in a manner approved by the state society, to undertake and coordinate all sickness care of indigents and low income groups, through contracts with public officials, and with physicians and others, and by the use of contributions, cooperative funds and other means, provided only that free choice of physician within such contracts shall be retained and that responsibility of physician to patient and all other contract and tort relationships with patient shall remain as though the dealings were direct between physician and patient."

Society News—Drs Ernest M Hammes, St Paul, and Walter A Fansler, Minneapolis, were guest speakers at the spring meeting of the Tenth District Medical Society at Rice Lake recently on "Differential Diagnosis Between Functional and Organic Neurologic Diseases" and "Injection Treatment of Hemorrhoids," respectively.—Dr George H Ewell, Madison, was elected president of the Wisconsin Urological Society at its spring meeting in Stevens Point recently. Speakers included Drs Walter G Sexton, Marshfield, on "Use of Concentrated Sodium Chloride Solution in the Control of Bleeding in Prostatic Resection", Walter M Kearns, Milwaukee, "Comparison of Results in Fifty Transurethral and Fifty Suprapubic Prostatectomies", and Erwin W Ewley, Minneapolis, "Replacement Lipomatosis of the Kidneys".—Dr Jacob L Bressler, Chicago, discussed "Orthoptic Treatment of Strabismus" before the Central Wisconsin Ophthalmological and Otolaryngological Society at Sheboygan, June 3.

GENERAL

Examinations in Obstetrics and Gynecology—Of 113 candidates examined by the American Board of Obstetrics and Gynecology in Atlantic City, June 10-11, eighty-nine were approved for certification, twenty-two failed and two did not finish the examination.

Special Examination in Ophthalmology—The American Board of Ophthalmology will hold an examination for certification in Cincinnati, September 17. Applications must be filed before July 15 with the secretary, Dr William H Wilder, 122 South Michigan Avenue, Chicago.

Hospital Association to Publish Journal—The board of trustees of the American Hospital Association at its May meeting approved a plan to publish a monthly journal to be called *American Hospitals* which will replace the present official *Bulletin* of the association. The first issue will appear January 1.

Society News—Dr Paluel J Flagg, New York, was elected president of the Society for Prevention of Asphyxial Death at the annual meeting in Atlantic City, June 12, and Dr Robert A Wilson, Brooklyn, secretary.—The third Pan-American Red Cross Conference will be held in Rio de Janeiro, September 15-26, it was originally planned for October 20-31.—The next meeting of the Pacific Coast Society of Obstetrics and Gynecology will be held in Los Angeles, November 6-9.

Public Health Campaign—A nation-wide campaign was launched, June 12, by the National Health Council to stimulate interest in community health on the part of the citizens and taxpayers, the *New York Times* announces. At the close of the

drive in October, open town meetings will be held throughout the United States to discuss public health. It was stated that the campaign is an attempt "to promote such special objectives in these communities as the local health and social agencies might think most desirable" and to coordinate all health and social agencies.

Dr Loeb Awarded the Phillips Prize—Dr Leo Loeb, since 1924 professor of pathology, Washington University School of Medicine, St. Louis, received the John Phillips Memorial Medal of the American College of Physicians at its annual session in Philadelphia, May 1. Dr Loeb delivered the convocation oration on "The Thyroid-Stimulating Hormone of the Anterior Pituitary Gland." The medal, established in 1930 in honor of Dr John Phillips, who lost his life in the Cleveland Clinic disaster in 1929, was awarded for the first time in 1932 to Dr Oswald T Avery of the Rockefeller Foundation and subsequently to Dr William B Castle of Harvard Medical School. The medals were presented to these men at the Philadelphia meeting. Officers elected are Drs Ernest B Bradley, Lexington, Ky., president-elect, Arthur R. Ellhott, Chicago, David P Barr, St. Louis, and Egerton L Crispin, Los Angeles, vice presidents. Dr James Alexander Miller, New York, was installed as president.

Medical Bills in Congress—Changes in Status S 883 has been reported to the House, with amendment, directing the retirement of acting assistant surgeons of the United States Navy at the age of sixty-four years (House Rept No 1388). *Bills Introduced* S 3152, introduced by Senator Wagner New York, proposes to provide compensation for disability or death resulting from injury to employees of interstate carriers. The bill provides that employers shall furnish employees medical surgical, hospital service, etc for accidental injuries arising out of and in the course of employment the employers being given the right to choose the physician who renders treatment. The bill further provides that no claim for any service rendered to a claimant in respect of any claim or award of compensation shall be valid against the claimant unless approved by the deputy commissioner. S 3153, introduced by Senator McNary, Oregon, proposes to provide pensions to veterans who served ninety days, in foreign service, under the jurisdiction of the Quartermaster General, Surgeon General of the United States Army the Secretary of the Navy, or Marine Corps, during the Spanish American War, including the Philippine Insurrection and the Chinese Boxer Rebellion. H R 8292 introduced by Representative Dorsey, Pennsylvania, proposes to establish certain rules for transporting dead human bodies in interstate commerce. The President is to be authorized to cause the Secretary of the Treasury to promulgate the rules and regulations set forth in the bill or to amend or change them as in his judgment may be in the interest of public health and welfare.

FOREIGN

Personal—The Medical Society of London presented the Gothergillian Gold Medal to Sir George Newman at its annual meeting, May 13. Sir George retired in March as chief officer of the British Ministry of Health and of the board of education. The medal is awarded by the society every three years.—Dr Wallace Ruddell Aykroyd, Dublin, has been appointed by the governing body of the Indian Research Fund Association director of nutritional research.

Lister Medal to Sir Robert Muir—The Lister Medal for 1936 has been granted to Sir Robert Muir, professor of pathology, University of Glasgow in recognition of distinguished contributions to surgical science. Sir Robert will deliver the Lister Memorial Lecture in 1936 at the Royal College of Surgeons of England. This is the fifth presentation of the award. A committee representing the Royal Society, the Royal College of Surgeons of England the Royal College of Surgeons in Ireland, the University of Edinburgh and the University of Glasgow makes the selection.

Society News—The International Society of Medical Hydrology will hold its annual meeting in Brussels Belgium, October 12-17.—The International Union for the Scientific Investigation of Population Problems will meet in Berlin, August 26-September 1. The general secretary of the union is Capt G H L F Pitt Rivers, London School of Economics, Houghton Street, London, W C 2.—The annual session of the Therapeutic Union, an international association founded in 1934, will take place October 9 at the University of Paris Faculty of Medicine. Among the subjects to be discussed are present knowledge of male hormones, surgery in arterial hypertension, and antimony compounds in therapeutics. Applications for membership may be sent to Dr G Leven, secretary, 24, rue Teheran, Paris (8).

Foreign Letters

(From Our Regular Correspondent)

June 8, 1935

Laboratory Examinations for Insured Persons

A defect of the national health insurance system is the failure to provide specialist services. Dr S C Dyke, honorary secretary to the Association of Clinical Pathologists, has addressed a memorandum to the *British Medical Journal* on laboratory examinations. He states that until comparatively recently medicine was practiced as an art but that it is now developing into a science, largely as the result of laboratory work, and specific treatment is available for a number of diseases. Examples are the uses of insulin, the antianemic principle of liver, and antitoxins. For the diagnosis of the diseases amenable to specific treatment, laboratory examinations are necessary, as in the diagnosis of pernicious from other forms of anemia. For lack of laboratory examination many cases of anemia not of the pernicious type are now uselessly treated with the antianemic principle, while others of that type are not diagnosed and do not get this treatment. Moreover laboratory examination is necessary for correct dosage of the antianemic principle.

The insurance system makes no provision for any form of laboratory examination. The panel physician may prescribe whatever he thinks necessary, but he is given no facilities for ascertaining, in the first instance, whether his diagnosis is correct and, in the second, the response of his patient to treatment. Representations have from time to time been made to the government by the British Medical Association and other bodies urging that modern methods of diagnosis and treatment made available by the laboratory should be at the disposal of the insurance system but so far without avail. In certain districts they have been made available by means of loopholes in the insurance acts, and for the reason that unallocated funds were available. In other districts 'the more active and intelligent practitioners' send patients to the voluntary hospitals for laboratory investigations, for which the hospitals receive no remuneration. The Association of Clinical Pathologists has for some years been urging the inclusion of laboratory examinations as a benefit under the insurance acts. It has drawn up a schedule of charges at which these can be performed without loss to the laboratories and this schedule has been adopted by the British Medical Association. The Association of Clinical Pathologists holds that clinical pathology can be properly carried out only in laboratories by pathologists attached to general hospitals. The hospital laboratories are the obvious centers for this work.

Precautions as to the Sale of Poisons

More stringent precautions in regard to poisons are urged in the report of the Poisons Board, just issued. Many fatalities, it is said, would be avoided if greater precautions were taken by the public in the keeping of poisons, particularly if it became the practice in every home for articles labeled "Poison" or "Caution" to be kept together in one place preferably under lock and key, away from other articles and out of the reach of children. A liquid poison should never be kept in an ordinary bottle, as it frequently is, but only in the bottle in which it has been bought. Poisons should always be labeled with an appropriate warning. The board proposes that the labeling provisions of the Poisons Act should be applied at every stage of distribution from the manufacturer downward. A type of bottle fluted vertically is suggested for liquid poisons other than those for internal use. In the case of particularly dangerous poisons no person, whether wholesaler or retailer, should be permitted to sell poisons to persons not known to him to be those to whom the poisons may properly be sold. The fact that the purchaser says that he requires a poison to sell again or for the purpose

of his trade or business is not sufficient to justify the sale to him with "no questions asked." In regard to drugs that can be sold only on a physician's prescription, the board recommends that the prescription should not be dispensed more than once unless the prescriber specially authorizes it.

"Broken Bones and Wasted Money"

In a previous letter (*THE JOURNAL*, March 16, p 934) the report of an expert committee appointed by the British Medical Association to report on the treatment of fractures was reviewed. The committee found that in consequence of want of organization the results were bad and the period of disability much prolonged. At a meeting of the National Safety First Congress, Mr E W Hey Groves, emeritus professor of surgery in the University of Bristol, read a paper on "Broken Bones and Wasted Money" in which he enforced the same lesson and advocated the organized treatment of fractures. He said that more than 150,000 cases of fracture occurred every year and that of these 100,000 were not treated in any organized clinic. To avoid all the muddle and inefficiency it was not necessary to provide a large special hospital devoted to accidents. There were three principles to be followed: unity of control, continuity of treatment and an efficient follow up. All the fractures that came to a hospital should be under the control of a fracture service having at least three surgeons. This team would involve the payment of salaries between \$1,250 and \$5,000 in addition to those paid to house surgeons at present. It would be a perfectly just arrangement if the insurance companies paid for the entire cost of the treatment of accidents. If they did, it was obviously in their interest to bring about such organization in the treatment of fractures as would involve unnecessary waste.

The Prevention of Automobile Accidents

The minister of transport stated in the House of Commons that in London, where the safety measures had been chiefly concentrated, there had been a reduction of 31 per cent in the number of killed and of 16 per cent in the number of injured during the last eleven weeks as compared with the corresponding period of last year. The corresponding reductions for the country as a whole were 16 and 11.5 per cent. Of 3,517 pedestrians killed on the roads in 1933 no fewer than 1,171, or one third, were children under the age of 15 years. Many of the accidents were due to the lack of playing grounds. He had decided on the immediate closing of certain London streets to automobile traffic except when proceeding to premises in those streets. The intensity of the campaign for road safety had not in any way checked the rapid extension of automobile traffic. At the end of February there were 224,000 more vehicles licensed than at the corresponding date in 1934 and 441,000 more than at the same period in 1931. Considerable progress had been made in the provision of nonskid surfaces. Much experimental work was being done in the attempt to produce a surface material that would remain nonskid for at least five years.

A Health Club for the Family

In Peckham, a district of South London, there has been established a medicosocial institution, which is of a quite new type even in this age of so much health organization. Three years ago, operations were begun by inviting families in the neighborhood to join a family club at a subscription of 12 cents a week per family. They were offered in return a periodic medical examination but no treatment. If and when necessary a note with the diagnosis was given the member for the family physician or for hospital treatment. In addition, members had the use of the club daily from 2 to 10 p.m. for social purposes. The experiment was so successful that it has been transferred to a much larger building, standing in a large area of grounds, designed for the purpose. This is neither a commercial venture

nor a charitable institution. It is in charge of two physicians who have made a special study of family health and who will be aided by voluntary workers.

The subscription is now 24 cents a week for each family, but much more is offered than the periodic examination—a swimming pool, gymnasium, boxing and dancing halls, cafeteria and library. There will also be a crèche, with room for perambulators, sewing machine room, a social club for mothers, garden space for games, infant solarium, lecture rooms and reading cubicles. The building has been designed for 2,000 families, and with a calculated revenue of \$50,000 it is thought that the cost of the building will be paid in thirty-five years. It is claimed that a periodic examination by the same physician results in a saving of 90 per cent of the serious cases among his patients. The unit of membership is the family as a whole, for it is held as a fundamental principle that physicians can only thus hope to acquire a full knowledge of the health of the individual.

Center of British Ophthalmology

The Royal London Ophthalmic Hospital—better known by its former name of Moorfields Hospital—is the largest eye hospital in the world and has long been famous as the center of British ophthalmology. The influence of its postgraduate teaching is world wide, and the great ophthalmic hospitals of India have been founded by men trained in it. Patients are attracted to it from all parts of the world. The hospital deals annually with 3,000 inpatients and more than 50,000 outpatients for which the working space became insufficient. A new outpatient department, which covers three-fourths acre has been added and is equipped in the most modern way. There is an orthoptic department for the treatment of squint by nonoperative methods and a physical therapeutic department for treatment with ultraviolet rays. In the pathologic department is a valuable museum and an ophthalmologic library of 5,000 volumes, the most complete in the world.

The New Cancer Institute of Paris

The striking feature about the new center for the treatment of malignant neoplasms is that there has been no effort made to avoid using the term "cancer" in designating the function of the new institute just opened in a suburb of Paris. The director is the pathologist Prof. Gustave Roussy. To all those familiar with his work this wise selection means efficiency in the full sense of the term.

The chief object was to concentrate, in close proximity to one another and under a single director, all activities pertaining to the diagnosis, treatment and research problems of neoplasms.

The buildings are in two groups, the laboratory under the supervision of the pathology department of the medical school, of which Professor Roussy is the head and also dean of the school. The second group is a series of hospital wards and private rooms, containing a total of 156 beds. In the main building, recently opened, are large consulting rooms for the outpatient service, treatment rooms for high voltage roentgen therapy and for curietherapy. The apparatus for the former method of treatment has a capacity of 300,000 volts and is in charge of Dr. M. J. Belot. The installation complies with all the requirements of modern technique. The service of curietherapy is under the direction of Mme. Simone Laborde, assisted by Y. L. Wickham and Mme. Liberson and has at its disposal 7 Gm of radium.

The six laboratories for diagnosis and research are in charge of competent cancerologists. Every known resource can be employed in this new cancer institute to combat the diseases for which it was founded.

Congenital Tuberculosis

At the meeting of the Pediatric Society, Nov. 30, 1934, an apparently authentic case of congenital tuberculosis was reported by Grenet and his associates. A woman, aged 36, in the eighth month of pregnancy who was admitted to the hospital, complained of severe headache. Soon afterward the clinical picture was that of a tuberculous meningitis.

A vaginal cesarean operation was performed and a living child weighing 2,600 Gm. was delivered. The mother died ten days after admission to the hospital.

The autopsy revealed a tuberculous meningitis and a bilateral pulmonary tuberculosis.

The infant was separated from the mother immediately after its birth and given by mouth the BCG vaccine, on the second, fifth and seventh days after birth. Sulpharsphenamine was also given, beginning the seventeenth day, because there was a history of maternal and paternal syphilis. Symptoms of enterocolitis appeared seven weeks after birth and rales over both lungs, a large liver and spleen were found. The child died at the age of 2 months.

The autopsy revealed a generalized tuberculosis and many typical tubercle bacilli were found in the lesions. The lungs, spleen, liver and kidneys presented a large number of milary nodules, which showed on microscopic examination typical tubercles with giant cells. Guinea-pig inoculations from the mesenteric lymph nodes and spleen were positive. The organism found was the human type of tubercle bacillus. The placenta was not examined, but the authors believe that there can be no question that infection of the fetus took place through the placental circulation.

A Report on Arteriography

At the April 10 meeting of the Société de chirurgie, dos Santos reported his experiences with 852 cases during the six years ended January 1935. Of these injections of an opaque medium 431 were made into the aorta and 421 into the arteries of the extremities. His paper was limited to the latter. The only accident in a total of 1,500 injections into peripheral arteries occurred in 1928 during an injection of the femoral artery with sodium iodide. On account of a hematoma, which increased constantly in size it became necessary to ligate the vessel. Recovery without gangrene took place. Puncture of an artery may be followed by vascular spasm especially in the upper extremity in younger individuals. It is necessary to avoid injecting the opaque medium into the tissues around the artery, to avoid gangrene of the periarterial structures. The injection should never be made with any force because it is this excess of pressure which entails vasomotor spasm. In the case of the arteries of the upper extremities it is advisable to expose them before injecting. In 129 arteriographies with iodine preparations an increased degree of gangrene was seen in six cases. In 300 arteriographies in which thorium dioxide sol was used, no local accident has been seen even in cases of gangrene, arteritis or aneurysm. Generalized symptoms large hematoma in the anal region, hematemesis, marked anemia and delayed coagulation time were observed in one case but recovery followed after injection of calcium and blood transfusion.

There have been no deaths in any of the cases in which arteriography of the extremities was done.

He quoted other authors (American and European) whose experience, added to his own constitutes a total of 1,300 arteriographies without any mortality. Arteriography is especially indicated before operations for arterial or arteriovenous aneurysms and for aneurysms of the peripheral vessels. In spite of the unfortunate accident reported by Leveuf of gangrene following arteriography in a case of Volkmann's contracture, dos Santos used the method successfully in five such cases. In four of these the information yielded by the method in Volkmann's contracture was of great value.

Legal versus Illegal Abortions

At the request of the minister of public health, a committee, of which Professor Brindeau was chairman, has been appointed by the Academy of Medicine, and the committee has just submitted its report. Illegal abortion should be discouraged because it plays an important part in depopulating a country. The majority of abortions in France are not seen by medical men. Patients are sent to hospitals when there is a complication, so that the number observed there are only a small portion of the total number. Professional secrecy plays a role because it prevents notice being given to the authorities. In a report made by a number of Russian gynecologists in 1927 covering a period of six and a half years, it was stated that the number of illegal abortions had increased in spite of legalizing abortion in that country.

Discussion of the report of Professor Brindeau took place at the academy April 2. Bar pointed out that it had been stated that the underlying motive of the Russian law legalizing abortion had been to combat secret operations. He thought that such a motive was secondary, whereas the primary one was to find an excuse to check the abnormally high birth rate, furthermore to give a woman the right to decide whether pregnancy was desired, and finally the rights of the state to determine whether or not more children were wanted. The only condition under which the prospective mother would be likely to wish to terminate the pregnancy would be on account of economic conditions. A commission of three had been appointed in Russia to determine whether pregnancy in the individual case should be interrupted or not. One member was a woman physician, a second a representative of the ministry of public health and the third an official who looked into the economic conditions of the case. The enormous increase in the number of legalized abortions in Russia shows that the commissions have not been very severe in considering the reasons presented by women to terminate the pregnancies. Even if the commission decides against a legalized abortion, the applicant has recourse to appeal. In order to diminish the risks of a legalized abortion, a limit of three months of pregnancy was adopted. The number of legalized abortions has risen from about 8,000 in 1922 to nearly 32,000 in 1926 in Moscow alone. Bar believes that Brindeau's report, which pointed out the dangers of abortion and advised against the adoption of legalized abortion in France, was to be endorsed in every particular.

Damage Suit for Death Following Arteriography

The active discussion that has been taking place at the Société de chirurgie regarding the merits and dangers of arteriography has been frequently referred to. The method was first proposed by dos Santos of Lisbon, Portugal, and consists in injecting a radiopaque solution directly into an artery to determine changes in the vessel wall and the level of blocking of the lumen in cases of thrombo angustis obliterans, arteriosclerosis and similar conditions. A recent decision in one of the courts of Paris awarding damages of 100,000 francs (about \$7,000) has called attention to the dangers of arteriography and the possible liability incurred by public hospitals and their staffs when an accident occurs in using such a diagnostic procedure. Prof. Camille Lian, a Paris internist, had under observation an ambulatory patient in his clinic, an elderly man suffering from intermittent claudication of the left leg for a year preceding the arteriography. To determine more accurately the vessel changes in this patient, Professor Lian sent for him in order to employ arteriography. The opaque medium used in this case contained thorium salts in colloidal solution. Immediately after the injection into the right femoral artery, the patient experienced such severe pain in the right limb that hospitalization was necessary. The following day, marked pallor of the right foot and a bluish discoloration of the calf of the limb were noted. Gangrene occurred five days later so that amputation of the right limb

below the knee became unavoidable. The patient died twenty-three days after the right arteriography.

The necropsy revealed a marked narrowing of the femoral artery of the left side, the injection having been made into the femoral artery of the right limb. At the point of narrowing of this left femoral artery, the lumen was still permeable. At the site of injection into the right femoral artery, the vessel was occluded by a thrombus. Professor Lian's defense against the damages claimed by the relatives of the patient was that the gangrene was not due to the injection but was the result of the arteritis for which relief had been sought a year before. The court stated that an untried diagnostic method had been employed, the potential dangers of which had not been sufficiently explained to the patient. In asking the latter to come back to the outpatient department, no mention had been made that arteriography was to be employed, only a radiography had been referred to in the letter to the patient. Although the injection had been made by two assistants who had a relatively large experience in arteriography, the court held that Professor Lian was the only one responsible for the death following the arteriography and must pay the entire damages to the family.

International Congress of Legal and Social Medicine

The twentieth annual meeting of the International Congress of Legal and Social Medicine will be held in Brussels from the 17th to the 20th of July. The subjects to be discussed include conflicting medical testimony, characteristics of wounds made during life or after death, postoperative complications of amputations, traumatic necroses, traumatic psychoses, and the relation of legal and social medicine. Information may be obtained from M. de Laet, 115 Boulevard de Waterloo, Brussels.

Seventh International Congress of Industrial Medicine

The seventh International Congress of Industrial Medicine will be held in Brussels, July 20 to 26. The subjects to be discussed will be end results of skull fractures, injuries of the hand, effects of dust in industrial occupations, pathologic action of gases escaping in coal mines, and lesions due to electricity.

Eighth International Congress of Military Medicine and Pharmacy

The following questions assigned for study at the seventh Congress of Military Medicine and Pharmacy, held in Madrid, will be taken up at the eighth congress at the Brussels meeting, to be held June 27 to July 3: principles of organization and functioning of medical services in mountainous countries, determination of aptitude of soldiers for various service branches, end results of abdominal injuries, standardization of methods of analysis of foods for soldiers, and distribution of various health services.

Death of Professor Morax

The ophthalmologist Professor Morax died in May. Although born in Switzerland, he began his medical studies in France, becoming early in his career an assistant at the Pasteur Institute, where his research work was done on the diplobacillus of subacute conjunctivitis (bacillus of Morax). Up to the time of his retirement from active practice, he continued to direct laboratory work at the Pasteur Institute.

Morax was the first to be appointed in charge of a special eye service, in the Hôpital Lariboisière, one of the free hospitals, where he worked for twenty-five years up to the time of his retirement in 1929. His courses in English have been attended by many Americans. During the World War his service became the ophthalmologic center for the French army. His contributions to the literature of his specialty have been recognized as of the highest merit. He was regarded as one of the greatest authorities on infections of the eye and of the conjunctiva. In 1923 he founded a society to study the prevention of trachoma, a disease in which he was particularly interested.

Bone Production from Transplanted Bladder Mucosa

Professor Gosset reported the experimental work of two of his associates, G Loewy and I Bertrand, at the meeting, Dec 5, 1934, of the Societe de chirurgie. Forty-two transplants of various tissues were carried out on twenty-two dogs. In thirteen autotransplants of the epithelial lining of the bladder, the ureter or the renal pelvis, bone formation occurred in all the experiments. In seven experiments, homotransplants (from dog to dog) were used. The grafts were not composed of living tissue, having been placed in 60 per cent alcohol. No bone formation followed in any of the seven dogs. In eight experiments, living tissue of the urinary tract was transplanted from dog to dog without any resulting bone formation. Eight autotransplants of living epithelial lining of the gallbladder also failed to develop bone. The same was true of living autografts taken from the epithelial lining of the stomach and small intestine, as well as autografts taken from the liver, pancreas and spleen.

These experiments explain the relative frequency of bone formation in the scars following cystotomy.

Measures to Combat Tuberculosis

The campaign against tuberculosis had until recently been left to the *krankenkassen*, the social insurance carriers, and the welfare bureaus—and, in addition, to the tuberculosis relief centers, which are designed to ferret out all open cases of tuberculosis. Now the Nationalsozialistische Volkswohlfahrt, commonly called the NSV, has turned its attention to tuberculosis influenced by the observation that the number of tuberculosis patients is so great that the aforementioned organizations are unable to care for all of them. It is estimated that 2 per cent of the population of Germany—about 1,320,000 persons—are affected with unarrested tuberculosis and that from 0.5 to 0.7 per cent, or about 400,000 persons, have open tuberculosis.

In Germany's previous organization for the combating of tuberculosis there were many defects. There are numerous small industrialists, artisans, farmers and representatives of the liberal professions who are not insured and who have not sufficient means to pay for an adequate course of treatment. Then, too the insurance carriers frequently refuse to grant funds for a course of treatment if there is no prospect of the patient becoming able to earn his living. After treatment and restoration of earning capacity, a patient often returns to an environment in which he very soon falls a prey to a new infection.

The NSV seeks not only to effect a cure of the individual patient but endeavors to eliminate also the sources of infection, that is, it attempts to ferret out those cases which are not likely to be discovered by any other agency and cases in which funds are not granted by the insurance carriers. If another welfare organization has refused to sponsor a course of treatment, it will make an investigation and, if conditions warrant, will endeavor to induce the organization to reconsider its decision, offering at times to share the cost of treatment. The NSV will usually arrange for treatment in a sanatorium if the patient has any prospect of recovering. The organization not only interests itself in the patient himself but also in his family. If the patient must travel to a more distant place for treatment, it will, if necessary, provide clothing and traveling necessities. During the patient's absence, the NSV looks after his family. Along with this aid of a pecuniary nature, there will be an extensive educational program, accompanied by lectures. It is hoped that, by the end of the year, all the German districts may be reached.

Likewise the federal league of German officials—the RDB—has created a welfare department for the aid of tuberculous

persons, which is managed in the following manner. The confidential secretaries of the local and district groups of the RDB are under obligations to introduce all colleagues in whose families there is tuberculous disease or a suspicion of tuberculosis to the relief center for tuberculous patients or to a specialist for tuberculosis. The organization of prophylactic curative or protective measures rests exclusively with the relief center or the tuberculosis specialist. The confidential secretary must see to it that the physician's orders are carried out. If difficulties arise, he must inform the social worker concerning the matter. If the prophylactic, curative and protective measures require an outlay of money, the confidential secretary will do his utmost to procure for his colleague the funds from the *krankenkassen* or other organization. Not until all these possibilities have been exhausted is the question to be raised as to whether and to what extent an allocation of aid by the RDB is desirable and feasible.

The Need of Midwives

According to recent statistics, of 956,000 births occurring in Germany in 1933 about 800,000 were in charge of midwives. For the year 1934 the number of births in charge of midwives is placed at 850,000. If one figures an average of fifty confinements a year for each midwife, there must have been about 17,000 midwives in active practice in Germany in 1934. These are merely estimates, the distribution of midwives in Germany is not uniform. There are regions with from eighty to 100 confinements to each midwife, as compared with others in which every village with no more than ten births a year has a trained midwife. Assuming that the average period of active service for a midwife is thirty-five years, it may be estimated, on the basis of the figures for 1934 that about 500 midwives should be graduated every year. Taking this estimate as a basis, from 7,000 to 8,000 more midwives than are needed have been trained. The situation is further clarified by the fact that in 1934, 1,180 midwives were newly registered while 1,150 more were pursuing a course of training. Hence, demands for the application of government control measures to this profession as well are being heard. The minister of the interior has, therefore, limited the number of pupils in the midwifery training schools to from 300 to 400. This number is considered adequate in view of the existing total of approximately 25,000 midwives.

The Notifiable Diseases in 1934

The trend of the notifiable diseases in the German reich in 1934 was not uniform. While not a single case of such diseases as typhus fever, leprosy, smallpox or relapsing fever was reported, the official statistics reveal an increase of infectious diseases of children. Diphtheria showed the greatest increase for the first time since the war, more than 100,000 cases having been notified in one year. Scarlet fever presented so many cases (particularly during the last quarter) that great anxiety has been felt. Epidemic poliomyelitis was kept fairly within normal limits, with a total of 1,700 cases. Typhoid presented a low morbidity in 1933 and 1934. The total number of cases of diphtheria in 1934 was 113,936, as compared with 74,559 in 1933 (*THE JOURNAL*, May 12 1934, p 1625). The number of deaths increased from 3,628 in 1933 to 4,799 in 1934. The morbidity from scarlet fever rose from 76,749 cases, with 546 deaths in 1933, to 110,706 cases with 789 deaths, in 1934. The case mortality remained in 1934 at the low level established in 1933 (0.71 per cent). The total number of cases of epidemic meningitis was 1,015, which is the highest record for any year since the war. The total number of deaths was 423 (42 per cent mortality), as compared with a mortality of 47 per cent in 1933. Poliomyelitis was represented by 1,700 cases as against 1,249 cases in 1933 and 3,733 cases in 1932. The mortality for 1934 was comparatively favorable (8.9 per cent, 10.5 per cent

in 1933) No estimate of the possible favorable effects of serotherapy can be made from the figures There were 128 lute injuries inflicted supposedly by animals suffering from hydrophobia There was one death, which is not essentially different from the mortality of recent years Anthrax declined further in 1934 (seventy six cases as against eighty-three in 1933), although the mortality was higher (fourteen deaths, ten in 1933) The cases of puerperal fever rose from 4,826 in 1933 to 5,886 in 1934 It must be considered, however, that there was a marked increase in the birth rate The increase in the number of births was proportionately greater than the increase in the number of cases of puerperal fever, the former increase being doubtless due to the decrease in the number of criminal abortions The new cases of trachoma declined from 866 in 1933 to 728 in 1934

Importance attaches to the statistics on pulmonary tuberculosis In 1934 Prussia reported 41 579 new cases and 21,298 deaths A comparison with the averages for the past ten years reveals a steady improvement Epidemiologic developments in the morbidity of tuberculosis of the respiratory organs are especially pleasing, because tuberculosis demands annually more victims than all the other infectious diseases taken together

Government Aid to Married Couples

According to recently published figures, the German reich had made, up to 1934 a total of 366,178 loans to newly married couples (*THE JOURNAL*, April 21 1934, p 1315) During the same period, a total of 143 571 living children were born to couples who received loans with which to finance their marriage.

In the second half of 1934 the number of marriages was 131,000 greater than in the second half of 1932, although for the former period only 89 680 loans were made. At least one third of the increase in marriages during the period mentioned was due to the stabilization of political and economic conditions In the fourth quarter of 1933 more than half (52.9 per cent) received marriage loans in the fourth quarter of 1934 only a fifth (20.3 per cent) In the first quarter of 1934 the number of children resulting from marriages made possible by the aid of federal loans amounted to 86.5 per cent of the whole birth increase, in the second quarter only 59.5 per cent, and in the fourth quarter about half These facts point to an increased interest in marriage and a greater willingness to have children, which are manifest independent of marriage loans

NETHERLANDS

(From Our Regular Correspondent)

May 7, 1935

Reeducation of Handicapped Persons

An interesting article by J Kastelein, special agent of the Rijkverzekeringsbank gives a detailed account of what can be accomplished through reeducation of handicapped persons The four chief factors to be taken into account are (1) the nature and the extent of the infirmity (2) the occupation, (3) the patient's age, degree of intelligence and attitude toward work, and (4) the chances of finding in his new employment adequate means of subsistence.

Of the 307 requests received twenty were withdrawn and 126 were refused One hundred and sixty-one or 52.5 per cent, of the petitions were granted Thirty-seven cases of reeducation were abandoned, four at the request of the patients and nine for other reasons Something more than half of the 52.5 per cent of the accepted cases or about 25 per cent of the total number of requests for instruction, were crowned with success Most of the cases abandoned by the management were due to lack of interest on the part of the candidates, to insufficient progress or to bad conduct Some wounded or injured workmen have no desire to learn a new trade others cannot accustom themselves to a new environment. The average duration of the reeducation process (after the injury) is three years and six months One fifth of the persons were able to resume their

usual occupation after completed reeducation The author gives the distribution of the cases among the provinces of the Netherlands The largest number of cases of reeducation were found in the province of Overijssel whereas in the province of Utrecht not a single case turned out satisfactorily

The Population of the Dutch East Indies

The European group of the population of the Dutch East Indies numbers 240,417 or about 0.4 per cent of the total population The favorable economic conditions in the Indies have enabled Europeans to marry and to bring their wives to their new home Hence the number of women residing permanently in the Indies has increased Fifty-four per cent of the Europeans live in the cities in spite of the increasing number of industrial and agricultural enterprises established in the country Seventy per cent of the Europeans residing in the Indies were born there. Twenty-one per cent were born in the Netherlands The percentages from various other countries are small About 8,000 European children born in the Indies are sent to Europe to complete their education

Leaving the army out of the count, there were scarcely 2,000 Europeans in Java and Madoera in 1814, in 1823, about 6,000, in 1836, 11,345, in 1845, 16,270 The population doubled between 1860 and 1900 Between 1900 and 1930 it increased two and one-half times During the past ten years the number of marriages has likewise increased. The number of births is small 163 per thousand households Two per cent of adult European males and 7 per cent of the women are illiterate The principal cause is the fact that school attendance (or private instruction) is not compulsory As to the religious beliefs of the population, there are 1,000 Jews, 1,400 Mohammedans 120,000 Protestants, 77,000 Catholics, 8,500 Asiatics (many of them Buddhists), 17,000 with no religion, and 18,000 whose religion is unknown

Ultraviolet Rays in the Treatment of Leprosy

About four years ago Dr Denis Mulder director of a radiologic institute in the Dutch East Indies, after effecting in three years the cure of a leprosy person with the aid of ultraviolet rays, called attention to this mode of treatment Following his report, funds raised through the generosity of private donors were devoted to the application of the method on a large scale (in the colony of Pelantoengan), but the scientific control of the trials was not sufficient to justify the formation of any final opinion on the value of the method Later, the government of the Dutch East Indies commissioned Dr P H J Lampe to render a report on the subject which has now been published The report merely recalls the first evidences of success and emphasizes the impossibility of drawing any final conclusions as yet. Further trials have been undertaken in various leprosariums under the direction of the public health service

BCG Vaccination

Mr Heynsius van der Berg, the director of the Netherlands society for the combating of tuberculosis, has given an account of the results of BCG vaccination in the Netherlands He incorporated his account in his course on tuberculosis, delivered at the University of Amsterdam Excerpts from his survey follow

Over a period of eight and a half years, the BCG vaccine has been administered to 1,100 infants No harmful effects have been observed The vaccine is applied soon after the birth of the child During the first ten days a dose of 10 mg of vaccine, corresponding to 400 million living tubercle bacilli is ingested by the digestive tract, fasting The mortality from tuberculosis in children under 1 year of age ranges between 27 and 8 per cent for unvaccinated children and between 11 and 22 per cent for BCG children During the first two years the mortality rates for the unvaccinated and the vaccinated were from 38 to 18 per cent for the former and from 13

to 27 per cent for the latter. The general result is very satisfactory, but he points out that, in spite of vaccination, a number of BCG children become affected with tuberculosis, of slow evolution, but if it is malignant the children die. The prognosis for the first year for unvaccinated infected children appears to be bad, from 54 to 51.5 per cent died from tuberculosis. The mortality among the BCG children ranged between 28 and 58 per cent. This great difference of from 88 to 457 per cent indicates that the BCG children have a greater resistance to infection with virulent tuberculosis bacilli than the unvaccinated children.

The statistics of the Netherlands tuberculosis service took account of the danger of contagion to which the children are exposed after vaccination. This factor is often neglected in the statistics of other services published heretofore, although important for purposes of comparison.

April 15, 1935

Sunlight and Skin Reactions to Tuberculin

Luzzatti of Novara has made an extensive study of the influence exerted by sunlight on skin reactions to tuberculin. On the basis of results secured by the Società di cultura medica of Novara and tuberculin skin tests performed on children who were in a colony for heliotherapy, he affirms that the life in the open air and the prudent exposure to the sun's rays increase the skin reaction to tuberculin and may render exudative the proliferative reaction. The positive skin reaction is more frequent in females (37.5 per cent) than in males (17.9 per cent). Positive reactions are often found in subjects with a positive familial anamnesis. Tuberculous allergy results from factors external to the individual and is increased by a sojourn in a colony for heliotherapy. In such colonies, skin tests applied to children may indicate the limits for the exposure to climatic stimuli. Colonies in which the amount of stimulation is not such as to produce anergy but rather a highly allergic state is brought about in children may be regarded as exerting a specific influence in the crusade against tuberculosis.

The Medical Association of Trieste

The Medical Association of Trieste met recently under the chairmanship of Professor Ravasini. Professor Nasso, director of the pediatric clinic of the University of Milan, spoke on the clinical observations and results of research on diphtheria. Since 1926 in almost all the countries of Europe there has been a reduction of the morbidity and mortality from diphtheria. The speaker sought to explain the causes of this reduction and called attention to the importance of predisposing factors of a climatic and meteorological nature, the influence of which on the epidemiology of diphtheria is becoming more evident. Professor Nasso refuted the statements of those who cast doubts on the efficacy of serotherapy because of the therapeutic failures recently observed in specially malignant cases. He emphasized the need of more widespread prophylactic vaccinations with anatoxin to reduce to a minimum the receptivity to the disease.

Marcovich explained a new method of research in diseases of the peripheral arteries. Although the speaker affirmed the great sensitiveness of thermo-oscillometry, which enables one to detect lesions in limbs apparently sound, he denied the assertion that this means of research made it possible to distinguish between the various disorders, and he emphasized particularly that it has no value in differentiating prevaricating nervous lesions of the limbs.

Macchioro reported the results of his research on patients with diabetes mellitus to determine the possible relationships between the external and internal secretions of the pancreas.

In twelve patients he studied the behavior of the glycemic curve and of the diastase content of the blood and the urine, using substances with a pharmacodynamic action and also other substances, such as hydrochloric acid and dextrose administered by the oral and the intravenous routes. He affirmed that the existence of a true and proper correlation between the esocrine and the endocrine secretion of the pancreas cannot be asserted.

Diphtheric Paralysis

Prof. Cesare Cocchi, pediatrician of the University of Florence, has presented to the Accademia medico-fisica of Florence a hypothesis, supported by anatomic and physiologic data, that would explain why, in all persons affected with diphtheric paralysis, and particularly in children, paralysis of accommodation is present. According to Cocchi, a selectivity of the toxin for the nucleus of the oculomotor nerve is not involved but rather a mechanism of different action. The function of accommodation is associated with two antagonistic systems, one neuromuscular and the other connective-elastic, and since the diphtheric toxin acts in a selective manner on the neuromuscular system, the speaker holds that the evidences of involvement of the nervous system are seen primarily and with greater frequency in the accommodation system, in which only one of the antagonistic systems is neuromuscular. When, however, there are two systems with opposite action but both neuromuscular, the toxin acts in equal measure on both and the external clinical effects are wanting or are revealed with minor intensity, for, although there is paralysis, the functional equilibrium will not be lacking.

Prof. Gaetano Corrado

The death of Prof. Gaetano Corrado, emeritus professor of legal medicine at the University of Naples and one of the prime movers in restoring forensic medicine to its former place of dignity and importance, is announced. His researches concern examination of the sternum for the determination of the age of the fetus and the new-born, the principal nuclei of ossification that may be found at the time of birth, the spectroscopy of living and dead tissues and its application to the study of certain forms of poisoning, also the examination of the nerve cells in death due to electricity, mummification, and various matters in the field of teratology. He was twice president of the faculty of medicine of Naples and had served as president of the Academy of Medico-surgical Sciences. He founded a museum of legal medicine, which contains various collections and some specimens of exceptional importance.

Marriages

ROBERT SHERMAN BALDWIN, Marshfield, Wis., to DR. ELIZABETH ALICE REDDEMAN of Milwaukee, June 1.

MYER J. GROSSMAN, Goshen, N. H., to Miss Charlotte Zeltzman of Dorchester, Mass., June 16.

STILES DEAN EZELL, Middletown, N. Y., to Miss Jane Manewal of Bessemer, Pa., June 18.

WILLIAM HARVEY HANKS, Greenwood, Del., to Miss Kathryn Phillips of Georgetown, April 13.

ZEPH J. R. HOLLENBECK, Columbus, Ohio, to Miss Elizabeth R. Jones of Jackson, June 15.

A. BROMLEY YORK, to Miss Bertha Hutchinson, both of Huntington, W. Va., May 2.

GUY SYDNEY McCLELLAN, to Miss Lucy Dell Leathers, both of Nashville, Tenn., June 4.

JOHN R. SWAN, to Miss Mary Esther Hughes, both of Indianapolis, June 15.

WILMOT BROWN ALLEN, to Mrs. Mary Fant Williams, both of New York, June 19.

JOSEPH E. MOTT, to Miss Eileen C. McManus, both of Pater-son N. J., June 5.

Deaths

Charles Russell Bardeen * Madison, Wis. Johns Hopkins University School of Medicine, Baltimore, 1897, since 1904 professor of anatomy and since 1907 dean, University of Wisconsin Medical School, where he developed the preceptor system assistant in anatomy 1897-1899, associate 1899-1901 and associate professor 1901-1904, at his alma mater member of the Committee on Central Scientific Exhibit of the American Medical Association since 1927 member of the American Association of Anatomists and the Wisconsin Academy of Science, a frequent contributor to anatomic journals aged 64, died, June 12 of carcinoma

Clifton Brooks Willmott * Louisville Ky., Kentucky University Medical Department, Louisville 1904 associate clinical professor of dermatology and syphilology University of Louisville School of Medicine, served during the World War on the staffs of the City Hospital, Children's Free Hospital, SS Mary and Elizabeth Hospital and the Kosair Crippled Children Hospital, aged 55, died May 18, in St. Anthony's Hospital, of intestinal hemorrhage

Frederick Epplen * Seattle Rush Medical College, Chicago, 1906, fellow of the American College of Physicians, member of the House of Delegates of the American Medical Association, 1923-1924 and 1928-1929 formerly secretary of the Pacific Northwest Medical Association at one time chief of the pathology department of the King County Hospital Seattle, aged 55, died May 25, of angina pectoris and arteriosclerosis

George Paul Sandrock * Major M. C., U. S. Army, Carlisle Pa. Chicago College of Medicine and Surgery 1916 served during the World War entered the medical corps of the U. S. Army in 1920, was promoted to captain in 1922 and in 1931 to major, aged 45, died, June 2, in the Walter Reed General Hospital Washington, D. C. of embolism, following an operation for perforated duodenal ulcer

Robert Paine * Memphis Tenn. Jefferson Medical College of Philadelphia, 1917 member of the Radiological Society of North America, instructor in roentgenology, University of Tennessee College of Medicine served during the World War, aged 42 on the staffs of the Memphis General Hospital and the Methodist Hospital, where he died May 26, of lobar pneumonia

John Gabriel O'Malley, Chicago, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1912, member of the Illinois State Medical Society served during the World War on the staff of the Columbus Hospital aged 46, was found dead in bed, May 24, of coronary thrombosis and diabetes mellitus

Henry Charles Babcock * Miami, Fla., Louisville (Ky.) Medical College, 1896, Kansas City (Mo.) Hahnemann Medical College 1913, Eclectic Medical University, Kansas City, Mo., 1914, Kansas City (Mo.) College of Medicine and Surgery, 1916 aged 61, died, May 26, in a local hospital, of a self-inflicted bullet wound

Ross D. A. Gunn * Oberlin, Ohio, Western Reserve University Medical Department Cleveland 1887 past president of the Lorain County Medical Society, formerly on the staff of the Allen Hospital, Oberlin College, aged 76, died, June 7, of coronary heart disease.

David John Marshall, Columbus Ind. University of Louisville (Ky.) Medical Department, 1891 member of the Indiana State Medical Association past president of the Bartholomew County Medical Society aged 70, died, May 10 of carcinoma of the gallbladder

Julian C. Baum, Poplar Branch N. C. College of Physicians and Surgeons, Baltimore 1894, member of the county board of education aged 64, died May 12, in the Hospital of St. Vincent de Paul Norfolk Va. of cerebral and gastric hemorrhage.

Bartholomew Lefkovicz, New York, Magyar Kiralyi Pazmany Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest Hungary 1886 member of the Medical Society of the State of New York aged 71 died May 19, of coronary thrombosis

David Russell Brown, Concord N. H. University of Vermont College of Medicine Burlington 1903 served during the World War aged 55, on the associate staff of the Margaret Pillsbury Hospital, where he died May 5 of uremia and nephritis

John Joseph Dorsey, Kansas City Mo. Columbia University College of Physicians and Surgeons New York 1907

member of the Missouri State Medical Association, aged 49, died, May 1, in St. Mary's Hospital, of tuberculosis of the lungs

Herman Winford Bundy * Kankakee, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908, on the staff of St. Mary Hospital, aged 55, was killed, May 19, in an automobile accident

Thomas Johns Robinson * Taunton, Mass., Harvard University Medical School, Boston, 1891, formerly member of the board of health, on the honorary consulting staff of the Morton Hospital, aged 69, died, May 5, of arteriosclerosis

George F. Converse, New Haven Conn., Yale University School of Medicine, New Haven, 1887 member of the Connecticut State Medical Society, aged 72, died, June 4 in the New Haven Hospital of carcinoma of the stomach and liver

William Wallace McRae * Corinth, Miss. Memphis (Tenn.) Hospital Medical College, 1894 aged 70, medical superintendent of a hospital bearing his name, where he died, May 5, of a head injury received in an automobile accident

Harrell Hardy * Poteau, Okla., Louisville (Ky.) Medical College, 1907 secretary and past president of the Lelore County Medical Society, aged 53, died May 22, in St. Edwards Mercy Hospital, Fort Smith, Ark., of acute appendicitis

Sylvan H. Likes * Baltimore College of Physicians and Surgeons, Baltimore, 1893, member of the American Urological Association, fellow of the American College of Surgeons, aged 64, died, June 5, of chronic nephritis

Edgar Savidge, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1896, aged 62, died June 7, in the Graduate Hospital of the University of Pennsylvania, of acute yellow atrophy of the liver

Louis Kunz, New York Bellevue Hospital Medical College, New York, 1898, member of the Medical Society of the State of New York, aged 61, died, May 11, in the Lenox Hill Hospital, of peritoneal carcinomatosis

Henry M. Fitzgibbon, Omaha John A. Creighton Medical College, Omaha 1908, member of the Nebraska State Medical Association, served during the World War, aged 56, died, May 9, in St. Joseph Hospital, of heart disease

William F. Beyer, Punxsutawney, Pa., Jefferson Medical College of Philadelphia, 1879, member of the Medical Society of the State of Pennsylvania, aged 84, died, May 24 in the Adrian Hospital, of perivesical abscess

Francesco Cannito, Providence R. I., Georgetown University School of Medicine, Washington D. C. 1934, aged 27, intern at St. Mary of Nazareth Hospital, Chicago, where he died April 3, of cerebral embolism

Bartlett Kniffin Menefee, Covington, Ky., Louisville Medical College, 1893 member of the Kentucky State Medical Association, served during the World War, aged 70 died, May 20, of a self-inflicted bullet wound

Luther Addison Robertson * Danville, Va., University College of Medicine, Richmond, 1900, on the staff of the Memorial Hospital, aged 60, died, May 16, in St. Luke's Hospital, Richmond, of embolism

Thomas G. Smith, Brownsburg, Ind. Central College of Physicians and Surgeons, Indianapolis, 1897 member of the Indiana State Medical Association, aged 71, died, May 26, of cardiovascular renal disease

Frederick Chipman Hemeon, Boston Jefferson Medical College of Philadelphia 1897 member of the Massachusetts Medical Society, aged 66 died May 26, of chronic myocarditis and arteriosclerosis

Delno E. Kercher * Philadelphia, University of Pennsylvania Department of Medicine Philadelphia 1895 on the surgical staff of the Methodist Episcopal Hospital, aged 66, was found dead, May 6

James Michael Reilly, New Haven Conn. Yale College Medical Department New Haven, 1878 member of the Connecticut State Medical Society, aged 79, died May 26, of chronic nephritis

Benjamin Franklin Uran, Kankakee Ill., Bellevue Hospital Medical College, New York 1872 member of the Illinois State Medical Society aged 87 died, June 10, in St. Mary Hospital of myocarditis

William Joseph Hosford, Santa Cruz Calif. Colorado School of Medicine Boulder 1890 veteran of the Spanish-American and World wars, aged 67, died May 3 of carcinoma of the stomach

William Elliott Brown, Indianapolis University of Michigan Department of Medicine and Surgery Ann Arbor 1895, aged 71 died May 16 of dilatation of the heart and cirrhosis of the liver

William Henry Guilfooy, New York, Bellevue Hospital Medical College, New York, 1889, for many years registrar of records of the city department of health, aged 75, died, May 23, of pneumonia

Alexander Marcus ♂ Newark, N J, University of Buffalo School of Medicine, 1929, aged 33, died, May 27, in the Newark Beth Israel Hospital of lobar pneumonia, empyema and endocarditis

David Telesphore Berube, Augusta, Maine, Maryland Medical College, Baltimore, 1912 on the staff of the Augusta General Hospital, aged 47, died, April 21, of coronary thrombosis

Charles D Gardiner, Grand Tower, Ill, Hospital College of Medicine, Louisville, Ky, 1877 aged 81, died, May 15, in a hospital at Murphysboro, of injuries received in an automobile accident

James Henry Kitchens, Jonesboro, Ark Missouri Medical College, St Louis, 1877, aged 83, died April 27, in the Baptist Memorial Hospital, Memphis, Tenn, of cerebral hemorrhage

David Morton Seymour, Bushnell, Fla, University of the South Medical Department, Sevanee, Tenn, 1909, formerly mayor of Bushnell, aged 53, died, April 21, of pneumonia

George W Jones ♂ Lawrence, Kan, Bellevue Hospital Medical College, New York, 1890, medical director of the Lawrence Hospital aged 75, died, May 1, of carcinoma

John Calvin Huckins, Plymouth, N H, Baltimore Medical College, 1904, member of the New Hampshire Medical Society, aged 56, died, April 29, of a self inflicted bullet wound

Eldorado C Briggs, Wilmington, Ohio, Medical College of Ohio, Cincinnati, 1881, member of the Ohio State Medical Association, aged 81, died, May 27, of heart disease

McClure W Cowan, Parsons, Kan, New York Homeopathic Medical College 1880 member of the Kansas Medical Society, aged 79, died, May 21, of diabetes mellitus

Isaac Clark Soule, Kansas City Mo, Hahnemann Medical College and Hospital, Chicago, 1890, aged 75, died, May 4, of valvular heart disease and cerebral hemorrhage

William R Lincoln, Cleveland Heights, Ohio University of Pennsylvania Department of Medicine, Philadelphia, 1888, aged 73, died, May 24, of coronary thrombosis

Moses Katz, New York, Illinois Medical College, Chicago, 1899, aged 61, died, May 17, in the New York Post Graduate Hospital, of carcinoma of the larynx

John Waldo Snoke, Palo Alto, Calif Cooper Medical College, San Francisco, 1905, aged 57, died, April 12, of arteriosclerosis and cerebral thrombosis

John N Bartlett, Clarksville, Mo, College of Physicians and Surgeons Keokuk, Iowa, 1887, aged 72, died, April 27, in Jefferson City, of carcinoma

Elmer E Glover, Franklin, Ind. Indiana Medical College, Indianapolis, 1878 aged 81, died, May 10, of chronic valvular heart disease and influenza

Clement Bruce George, San Jose Calif, College of Medical Evangelists, Los Angeles, 1933, aged 26, died, May 12, of a fractured cervical vertebra

Grace Alfaretta Rowley Bradley, Bradenton, Fla, Hahnemann Medical College and Hospital, Chicago, 1894, aged 77, died, May 30, of carcinoma

Reuben Milton Biggs, Palmersville Tenn, Vanderbilt University School of Medicine, Nashville, 1877, aged 83 died, May 6, of angina pectoris

Helen Hughes Hiescher, Mankato, Minn, University of Minnesota Medical School, Minneapolis, 1896, aged 72, died, May 31, of meningitis

Horace Irwin Slater, Port Chester, N Y Cornell University Medical College, New York, 1933, aged 28, died, May 2, of Hodgkin's disease.

George Benjamin Haggart ♂ Alliance, Ohio, Homeopathic Hospital College Cleveland, 1892, aged 66, died, May 10, of cerebral hemorrhage

Elizabeth Cassidy, Denver, Northwestern University Woman's Medical School, Chicago, 1897, aged 64, died May 10, of arteriosclerosis

Daniel Stephen Neuman, Napa, Calif. Gross Medical College, Denver, 1895, aged 66, died, April 28, of chronic myocarditis

Clarence Loeb, Winnetka, Ill, Marion-Sims College of Medicine St Louis, 1899, aged 59 died, May 26, of dilatation of the heart.

Bureau of Investigation

THE RITHOLZ FRAUDS

The Post Office Finally Debars Some Crude Swindles from the Mails

Ten years ago the Ritholz mail-order quackery was dealt with at some length in this department of THE JOURNAL, July 25, 1925. A similar article, written for the public, appeared in *Hygeia* for August of the same year. At that time it was brought out that the National Watch and Jewelry Company run by four persons by the name of Ritholz was operating spectacle-fitting-by-mail concerns going under various names, such as "Ritholz Spectacle Company," "Chicago Spectacle House," "U S Spectacle Company," "Fitwell Spectacle Company," etc, etc. At that time the National Watch and Jewelry Company had the following personnel: Juda D Ritholz, President, Samuel J Ritholz, Vice-President, Morris Ritholz, Treasurer, Benjamin D Ritholz, Secretary and Manager.

Since that time some of the Ritholz family have continued to operate fraudulent concerns under such trade names as:

U S Spectacle Co	Dr Ritholz Optical Co
International Spectacle Co	Dr S J Ritholz Spectacle Co
International Spectacle House	Dr Ritholz Optical Co Inc
Dr Ritholz & Sons	Ritholz Spectacle Co
Ritholz Optical Co	Physicians & Surgeons Optical Co
Self Test Optical Co	Consumers Spectacle Co
World Optical Corp	Nn Way Optical Co
Shur Fit Optical Co	Capitol Spectacle Co
Clear Sight Spectacle Co	Nu Sight Spectacle Co

In November 1934 these variously-named companies were called on by the postal authorities to show cause by Dec. 10, 1934, why a fraud order should not be issued against them. The hearing was postponed from time to time, but was finally held Feb 20, 1935, at which time Benjamin D Ritholz appeared, accompanied by his attorneys. The hearing occupied nine days, and the transcript of the testimony comprises more than 1,600 typewritten pages. After all the evidence was in the Hon. Karl A Crowley Solicitor for the Post Office Department, declared that the evidence showed that the scheme operated under these various names was one for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and Mr Crowley, in a memorandum to the Postmaster General, recommended that a fraud order be issued against the various names listed above and, in addition, against the names of B Mack, Manager, and J G Kite, Sales Manager. On May 3, 1935, the Postmaster General issued the order closing the mails to these frauds.

HISTORY OF THE SCHEME

The Solicitor's memorandum to the Postmaster General detailing the evidence in this case is one of the longest that has even been brought to the attention of the Bureau of Investigation, covering 70 typewritten pages. While it is much too long to give here in its entirety, some of the facts brought out therein are of interest in showing how large-scale quacks (more than a million dollars a year) can for years operate through the United States mails and defraud the public. We give briefly Solicitor Crowley's details of the history of the scheme. It was started in December, 1919, under the name "Chicago Spectacle House," which sold, through the mails, spectacles and other articles, including watches.

1921—The first move on the part of the postal authorities to curb these swindles was in October 1921, when the Post Office Department charged the Chicago Spectacle House with making false representations in the conduct of its business. A month later Benjamin D Ritholz executed the first of several worthless affidavits in behalf of the Chicago Spectacle House. In it Ritholz stipulated that the practices complained of by the postal authorities would be abandoned and never resumed at any time in the future. The evidence shows that the Ritholz concern did not abandon the practices complained of.

1922—The second move by the Post Office Department was in December 1922 when Juda Ritholz, Samuel Ritholz, Morris Ritholz and Benjamin Ritholz were charged with the fraudulent

use of the mails. A month later Juda Ritholz and Benjamin Ritholz executed another of the famous affidavits. In this they stipulated that they would cancel all advertising under the names they were then using and promised to reorganize the business in corporate form that would definitely fix responsibility. They also promised to discontinue the use of more than one name. They apparently did neither.

1925—The third effort on the part of the postal authorities took place in September 1925, when they charged Juda Ritholz, Morris Ritholz, Samuel Ritholz and Benjamin D. Ritholz once again with fraudulent use of the mails under the names of no fewer than thirteen companies. On motion of the Ritholz attorneys the charges were dropped without a hearing, but a month later the Ritholz attorneys were advised by the Post Office Department that the advertising of the Ritholz outfit was violating the postal fraud statutes.

1928—Effort Number 4 of the Post Office Department was put forth May 4, 1928, when Benjamin Ritholz and his associates of the innumerable named companies under which they did business were charged again with misuse of the mails. Not to be outdone, Benjamin D. Ritholz was on hand with another affidavit stipulating a discontinuance of the objectionable practices. This stipulation seems to have been just as worthless as the previous ones.

1932—Post Office Effort 5 came in 1932 and once more Benjamin D. Ritholz and his associates were furnished with a memorandum charging fraudulent use of the mails. At the hearing the postal authorities produced thousands of complaints from dissatisfied customers who had failed to obtain the promised refunds from the Ritholz companies. By June 1933, Benjamin D. Ritholz had disgorged another affidavit, in which he promised to make refunds and proper adjustments to more than 1,200 complainants. As one might have expected from what has already been written, the Solicitor's memorandum states that "this promise on the part of B. D. Ritholz and his associates was not faithfully executed in accordance with its terms."

1934—The sixth effort on the part of the Post Office brings us down to the charge of November 1934 finally heard toward the end of February 1935. Benjamin D. Ritholz and his associates were charged in the operation of their mail-order spectacle-selling scheme with having violated both in letter and in spirit the sworn stipulations which from time to time they were permitted by the Post Office Department to file to avoid the issuance of fraud orders.

THE PRESENT BUSINESS

The Solicitor's memorandum also deals at some length with the present business and states that the evidence shows that Benjamin D. Ritholz together with his brothers Samuel Ritholz and Morris Ritholz, and his mother Ante Ritholz (the last-named taking no active part in the business but having a financial interest therein), operate not only a mail-order spectacle-fitting business but also some thirty-five optical stores and also a mail-order dental business!

The Postmaster at Chicago reported in November 1934, that the various Ritholz mail-order outfits were receiving on an average over 400 letters daily. The Solicitor of the Post Office Department then describes in detail the fraudulent methods used by these various named concerns in selling spectacles on the mail-order plan. The evidence demonstrated that in more than 80 per cent of the test cases the Ritholz companies failed to furnish the proper lenses even according to the alleged policy and practice of the Ritholz concerns. Only in a few of the simplest cases, where the lens-strengths for each eye for both reading and distance were the same, did the Ritholz concerns furnish the proper lenses. Yet the Ritholzes have claimed that

95 per cent of their customers are satisfied and received the proper glasses. Not only this, but where several test orders contained the *same measurements* for reading and for distance, the Ritholz companies filled such orders with spectacles containing *different lenses in each case*, the variations ranging as high as three to five diopters.

Reputable ophthalmologists called by the postal authorities to testify in the case of course proved conclusively that it is quite impossible to fit spectacles satisfactorily on the mail-order plan. The Ritholzes were said to have produced two witnesses as experts, one of whom claimed to be a consultant of the Ritholz concerns. The "consultant" was Everett R. Brown, M.D. who, according to the records of the American Medical Association, was born in 1891, holds a diploma from Loyola University School of Medicine, Chicago, 1916, and an Illinois license of the same year. Brown had the effrontery in December 1934 to send out letters to physicians on the stationery of the Physicians Optical Service at 1148 West Chicago Avenue, Chicago. This is the address of the Ritholz quackeries. Brown in his letters stated that the Physicians Optical Service would furnish physicians with a "new patented eye-testing instrument, test charts samples of glasses, etc." with "full explanation of their

Greatly reduced photographic reproductions of some of the numerous advertisements of the Ritholz concerns

use." Brown emphasized in the letter that "Testing of Eyes Belong to Physicians" and stated that "Opticians Do Great Harm."

Everett R. Brown according to the government's report, "discredited himself upon the stand, not only by his unwillingness to answer simple questions which he pretended not to understand but by continual evasion of questions and also by his ignorance of simple fundamental anatomical and physiological facts pertaining to the eye, and of other matters in which he claims to specialize." This same alleged expert also is said in the memorandum to have shown himself ignorant of the functions of the optic nerve, erroneously asserting that it furnishes the nerve supply for the various muscles of the eye. He was even unable to state on cross-examination the characteristics of compound astigmatism, which constitutes between 40 and 50 per cent of errors of refraction, saying that he never saw a case! In various other ways, it appears from the evidence submitted in the Solicitor's memorandum, he demonstrated his ignorance. Such ignorance, of course, might be expected of a physician who would act as expert for such quacks as the Ritholz concerns.

SUMMARY

The Solicitor, in summarizing the voluminous evidence, stated that the Ritholz concerns solicited and obtained remittances of money through the mails by fraudulently representing that they, the Ritholz concerns, took all the risk, when, as a matter of

fact, the customer took the risk. The evidence showed, further, that the so-called "Scientific Self-Tester" that the Ritholz people sent to prospective victims was neither scientific nor based on sound principles. The evidence also showed that although the Ritholz concerns claimed to have "perfected a system of fitting glasses by mail," yet Benjamin Ritholz himself conceded at the hearing that glasses cannot be fitted by mail. While the Ritholz companies claimed that there was "no guesswork to their system," the facts were the entire system was based on guesswork.

It was further brought out that the lenses furnished by the Ritholz concerns were (1) inaccurately and poorly ground, (2) were not of a proper strength, (3) were incorrectly placed in the frames, (4) in some instances were chipped, cracked, splintered and decentered, (5) that many of the "bifocals" were made by simply pasting or gluing an additional slip of glass on the lower segment of the lens, with the result that in some instances the glue was opaque and in others it was spotty, and in still others the segments or slips became detached. It was shown, also, that the claim that a "trained specialist" checked the lenses after the spectacles were assembled was false, the so-called checking actually being done by untrained office girls. Many other fraudulent elements in the scheme were dealt with at length in the memorandum.

The principal contention of the Ritholzes in the case was that their customers got exactly what they ordered. The postal authorities, on the other hand, stated that the evidence shows that this was false, the fact being that the customers did not get either what they had been led to believe they would get or what they ordered. Hence the fraud order debarring this pertinacious and impudent fraud from the use of the United States mails.

The story is a sorry one. How many millions of dollars the Ritholz concerns have taken out of the pockets of ignorant but hopeful people is not of record. From the public's point of view, the tragic situation is that closing the mails to the eighteen company names and to the manager, Mack, and the sales manager, Kite, is a rather feeble punishment to the Ritholz fakers, who, individually, can still use the United States mails. It would seem that if ever there was a case which called for criminal prosecution, this is it. It is to be hoped that the postal authorities will bring to a good finish a job that has extended over fourteen years, by attempting to put in the federal penitentiary those members of the Ritholz family who have been guilty of the swindles here set forth.

During the past year or two the Ritholz concern, in addition to its mail-order quackeries, has opened a number of retail stores. There are more than a dozen such stores in Chicago alone. Thanks to the energetic action on the part of the Chicago Better Business Bureau, all Chicago newspapers and radio stations have barred their columns and facilities to the advertising of the Ritholz stores. The street cars of Chicago are not so particular, they still carry blatant advertisements of the Ritholz retail establishments.

The Giant Irishman.—John Hunter, the eighteenth century leader of English surgery, anatomy and physiology, spent most of his fortune and energy in collecting the famous Hunterian Museum, which is now housed in the College of Surgeons, London. One of its most remarkable specimens is the great 7 foot 7 inch skeleton of the giant Irishman O'Brien, who died in London in 1783. The undertaker was bribed by Hunter with £500, and, while the escort was drinking at a certain stage on the march seaward, the coffin was locked in a barn. There, some men concealed by the accomplice speedily substituted an equivalent weight of paving stones for the body, which was at night forwarded to Hunter. He took it in his own carriage to his home in Earl's Court, where in order to avoid the risk of discovery it was immediately immersed in boiling acid, after suitable division, to obtain the bones. This accounts for the brown color of the bones today. Hunter prized this specimen above all others, and in his famous portrait by Sir Joshua Reynolds, part of the skeleton is prominently placed in the background.—Guttmacher, A. F. *Bootlegging Bodies. A History of Body-Snatching.* *Bull. Soc. M. Hist. Chicago* 4:353 (Jan.) 1935.

Correspondence

EXPRESSION OF APPRECIATION BY THE CANADIAN MEDICAL ASSOCIATION

To the Editor—It would be greatly appreciated by the members and friends of the Canadian Medical Association who were privileged to attend the joint meeting in Atlantic City if you would be kind enough to publish this letter in the columns of THE JOURNAL in order that an opportunity may be afforded us to express our very sincere appreciation and thanks to the American Medical Association, the Medical Society of the State of New Jersey, the Medical Society of Atlantic County, the Women's Auxiliary of the American Medical Association, and that great host of individuals, both men and women, who so graciously received and hospitably entertained Canadians during the course of the convention. Those of us who had the good fortune to be present realize fully the efforts that were put forth to make the meeting the great success it proved to be, and to each and every one to whom we are indebted we desire to say Thank You.

T. C. ROUTLEY, M.D., Toronto
General Secretary, Canadian Medical Association.

GRANULOPOIETIC EFFECT OF LIVER EXTRACT

To the Editor—In Queries and Minor Notes in THE JOURNAL, May 25, page 1928, in a discussion on leukopenia, it is stated that "liver extract and yellow bone marrow are reported to have stimulated granulopoiesis in a limited number of patients, but the rationale of this therapy is not yet clear" and, in another sentence, "leukopenia secondary to megaloblastic hyperplasia, as in pernicious anemia, is, of course, automatically relieved by liver following the restoration of normal erythroblastic marrow, but this is not due to any direct defect on granulopoiesis."

I want to call your attention to two papers that, I believe, established without a question of doubt the granulopoietic stimulating effect of liver extract administered parenterally. I doubt very much that animal experimentation can establish the stimulating effect of any substance in this respect more clearly than these papers do. The references are Powers, J. H., and Murphy, W. P. *Leukocytosis Following the Intramuscular Injection of Liver Extract*, *J. Clin. Investigation* 12:713 (July) 1933, and Myer, O. O., Middleton, W. S., and Thewlis, Ethel M., *Am. J. M. Sc.* 188:49 (July) 1934.

WILLIAM P. MURPHY, M.D., Boston

ETHYLENE ANESTHESIA

To the Editor—One of the most regrettable incidents relating to surgery in the United States is the discarding of the most successful of all inhalation anesthetics by the majority of hospitals because of explosions in its use. I refer to ethylene. There is practically no danger if the anesthetic is properly safeguarded from static ignition, and this is too easily done to sacrifice the benefits of this wonderful agent. Complicated apparatus with tubes and compartments that cannot be reached by the humidity from rebreathing and thus eliminate or dissipate all static has brought about these explosions. Hence the type of apparatus used was inherently the danger, as this gas has been used by other methods so extensively without ignitions that the statement may be made that this fact is well proved. In Baylor University Hospital, ethylene has entered into from 95 to 98 per cent of all general anesthetics since October 1923, with use of the simplest possible device, consisting only of a rebreathing bag and attached face piece. Nitrous oxide-oxygen

is started with and the ethylene is added after consciousness is lost. The relative humidity in the apparatus is 100 per cent after the first five or six breaths are exhaled into the bag. As from 55 to 65 per cent relative humidity positively dispels static electricity, this method removes all possible danger. This simplified type of apparatus can be used with perfect safety. Let the people have the advantages and safety of this superb anesthetic, which is far superior to nitrous oxide oxygen with ether added, as is now so widely used since ethylene has been so unnecessarily discarded. About 200 other hospitals in Texas are using ethylene gas in the same manner.

JAMES G. POE, M.D.,
Baylor University Hospital,
Dallas, Texas

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF UNDERSIZED CHILD

To the Editor—A boy, aged 14 years was brought to my office for examination and treatment because of his small size and lack of weight. He is 55½ inches (140 cm) tall and weighs 59½ pounds (27 Kg) with his shoes, pants, socks and undershirt on. His mother and father both are of normal height but are noticeably thin. One brother and one sister are of normal height and weight for their age groups. The father was rejected for service in the army because of his weight; he weighed 110 pounds (50 Kg) at 21 years; his height is not known. The boy's past history is essentially negative. His birth weight is not recalled. He has had chickenpox and measles. The tonsils and adenoids were removed at 10 years for adenoid obstruction with relief. He always has seemed healthy though small. He has no complaints at present except for occasional styes on each eye. The cardiorespiratory, gastrointestinal and genito-urinary systems are normal. He sleeps well. He is in the first year of high school and obtains better than average grades. He has no unusual dietary habits and eats with relish a dietary that is obviously adequate for an older sister and a younger brother. Physical examination yields little except for the obvious small size. He is thin; the ribs stand out and can be counted with ease. The eyes, ears, nose, mouth, throat, lungs, heart and abdomen are normal. There is no pubic hair but the genitals are only slightly less than the average size for his age group. There is copious hair on his arms. Examination of the urine shows no albumin or sugar. The sediment is negative except for urate crystals. Hemoglobin is 75 per cent, red blood cells number 4,880,000, white blood cells 8,700. Smear shows 70 per cent polymorphonuclears, 25 per cent lymphocytes, 4 per cent large mononuclears, 1 per cent myelocytes. The red blood cells and platelets appear normal. Is there any reason to think that the child is suffering from some endocrine disorder? Is he necessarily abnormal or merely one of the extremes of the normal? 2. Can he be made to gain weight and, if so how? Please omit name.

M.D. Massachusetts

ANSWER—The 14 year old boy in question, whose height is given as 55½ inches (140 cm), should have an ideal weight of 75 pounds (34 Kg) for this height according to the Baldwin tables. The average height for a 14 year old boy is 59½ inches (151 cm) and the ideal weight for this height is 90 pounds (41 Kg). The child is therefore short for his age group and underweight for his actual height and age. His father weighed 110 pounds (50 Kg) at 21 years of age, which is very light for this age and presupposes a slight bony frame. The mother is also said to be thin. With this available information it would be permissible to conclude that the boy is small and slight and follows the general body configuration of his parents. If this is accepted, in the absence of any confirmatory information one would see no reason to think that the child is suffering from an endocrine disorder.

2. It is noted that he has normal dietary habits and eats amounts equivalent to those of his sister and brother. If he should be put to bed, with absolute rest, and given a very high fat and carbohydrate diet, he could probably be made to gain some weight. However, as he seems to be in good health and leading an active normal life, it hardly appears justifiable to put him through a fattening process.

Recently extract of the pituitary gland has been employed, containing the growth hormone. Engelbach and Schaefer (*THE JOURNAL*, Aug 18, 1934 p. 464) report the use of this in the treatment of seven cases of dwarfism. The patients were from 7 to 18 years of age. They reported growth in the children

treated. Such studies are not very convincing, because it is well known that growth in height may normally take place during some seasons of the year and may be absent or retarded in others.

PAIN AFTER FUSION OPERATION ON SACRO ILIAC JOINT

To the Editor—An unmarried woman, aged 47 was operated on by a very competent and well known orthopedic surgeon of Atlanta about three years and three months ago for a chronic sacro-iliac subluxation and a fusion was done. Since the operation there has been constant aching pain in the lumbar region and the buttocks. The latter are so tender that she finds it impossible to make trips of any distance in her car. Roentgenograms of the vertebral column, both anteroposterior and lateral, by a good roentgenologist show good results from the operation and no signs of arthritis or anything else. Can you possibly give me any information as to what is causing all this pain? Fourteen months ago spurs were removed from the os calcis of each foot by another orthopedic surgery of the same city. Since the operation there has been swelling of both ankles and aching pain in the arches and dorsa and heels of both feet. The patient also complains of cramping of both feet especially the big toe of the right foot when the shoe is off. Recent roentgenograms have demonstrated the return of the spur on the left os calcis. What percentage of spurs recur after operation? Is it common or uncommon for them to recur? Can the condition be attended to medically by giving a diet low in calcium-containing foods to prevent further growth of the spur or is diet necessary at all to prevent this? Please omit name and address.

M.D., Florida

ANSWER—Taking it for granted that the fusion operation was performed on one sacro-iliac joint, there is in some cases considerable strain thrown on the other sacro-iliac joint and the lumbosacral joints.

It is also possible to have arthritis without positive roentgen signs. The cause of the pain in the lumbar region and buttocks and tenderness while sitting in an automobile may be due to local or referred causes.

Local conditions that should be considered are gluteal bursitis, myositis and postural disturbances, the referred conditions are arthritis of the lower lumbar, lumbosacral joints with sciatic nerve radiation, part of which may be superior gluteal nerve pain.

Concerning the feet, there is undoubtedly some circulatory disturbance of the feet and ankles and mechanical disturbances in the arches and plantar fascia. There may be a mechanical disturbance of the transverse arches.

In reference to the recurrence of spurs following operation we know of no figures of a series sufficiently large to justify a percentage basis. It is fairly common that recurrence of the spur may take place. There is no doubt that in many cases there is a metatarsal disturbance, and without the correction of this the operation is often unsuccessful.

EFFECTS OF BELLADONNA ON CHILD

To the Editor—Will you discuss the probable effect of the following prescription which was given to a baby aged 4 months weighing 10 pounds (4.5 Kg). The baby was suffering from a cough and cold and had no fever. Tincture of belladonna 3 drachms, elixir lactated pepsin sufficient to make 4 ounces. One teaspoonful every six hours. Please omit name.

M.D. Virginia

ANSWER—The dose of 6 minims of tincture of belladonna for a baby aged 4 months is excessive and may result in symptoms of atropinism, such as dilatation of the pupil, dry red throat and skin, rapid pulse and rapid respiration, with possibly fever and even delirium, a clinical picture that sometimes resembles scarlet fever.

PAIN AFTER CHOLECYSTECTOMY

To the Editor—Is there anything that can be done to help patients permanently who continue to have severe attacks of pain in the right upper quadrant from one to fourteen years after cholecystectomy? Is there any surgical intervention that would give much chance of success as cutting nerves or the sphincter of Oddi? I have tried such medical measures as weight reduction, high fat diet, low fat diet, normal diet, atropine, belladonna, bile salts, epsom salt, hot and cold water and olive oil without preventing the attacks. What combination works the best or is there anything new I could try? Please omit name and address.

M.D. Montana

ANSWER—In most instances of severe right upper quadrant attacks following cholecystectomy, if no stones have been found, the pains are due to a spasm or partial obstruction in the sphincter of Oddi and are usually cured by common duct drainage ranging from four to seven weeks. If stones were found in the gallbladder at the time of the cholecystectomy it is quite possible that some small stones have been overlooked in the

common duct, which was probably not opened and then, of course, the patient could suffer with repeated attacks of right upper quadrant pain without jaundice. This sometimes can be determined by examining the urine for bile immediately after the attack. Probably the best way to relieve such pains is to administer atropine sulphate. The patient will in all probability never be well until a thorough exploration is made of the common duct or drainage or common duct anastomosis is done.

POISONING FROM LEAD IN STORAGE BATTERIES

To the Editor—A man in his early forties, proprietor of a tire and battery shop, complains that the fumes from batteries charging and repairing, irritate the upper respiratory tract and he feels that they are important in the causation of a chronic bronchitis these symptoms are much exaggerated during the winter months when ventilation in the shop is inadequate. The shop is not equipped with hoods or other means of carrying the fumes away. The patient is underweight and there is a moderate secondary anemia. He complains of easy fatigue, flatulence and restless sleep. According to certain authorities men engaged in such work may suffer from lead poisoning. While admitting that part of the respiratory tract irritation is probably due to acid fumes and so on, can one consider that this man is suffering from lead poisoning on the basis of the evidence submitted? There is no lead line on the gums nor does the patient present other definite diagnostic criteria such as lead colic or wrist drop. An examination for stippled cells has not been made. The patient has been advised to wear a respirator while working over the storage batteries. If this is proper, what special type of respirator should be used? Please omit name. M D Ohio

ANSWER—In the largest of storage battery manufacturing plants, in the departments where batteries are charged, lead poisoning is unknown. Likewise the usual duties involved in the small type of battery shop ordinarily do not result in lead poisoning. The sulphuric acid employed in batteries does not readily evaporate, but acid vapors in small amount do find their way into the atmosphere, chiefly as a result of chemical ebullition, the breaking of countless bubbles at the surface of the liquid thrusting small quantities of the acid into the atmosphere. This acid in the atmosphere is irritating, may affect the teeth, may lead to irritation of the respiratory tract, and when swallowed with saliva may lead to gastric disturbances. From a practical point of view this occupational disorder is apparently not very important among the many hundreds of workers engaged in this phase of storage battery manufacture. In the building of storage batteries the hazard to lead poisoning is great but in ordinary repair work in small shops exposure is on a much lower plane. For this reason no justification exists for believing solely on the basis of the evidence submitted in the query that this worker is suffering from lead poisoning. Greater significance should be attached to the presence of acid vapors. The presence or absence of stippled cells in the blood is coming to be associated with lesser diagnostic importance than heretofore. The presence of reticulocytes or basophilic aggregation in excess of 1 or 1.5 per cent may be of more significance than the presence of a few stippled cells. The hazards under discussion are believed to be of such low magnitude that the wearing of a respirator may not be warranted. General exhaust systems are at this time regarded with greater favor for this particular kind of work.

EXPULSION OF MECONIUM IN BREECH PRESENTATION

To the Editor—In a recent case in which there was a breech presentation of the fetus, the bag of waters ruptured the meconium exuded from the vagina and small clots of blood came for ten days before the baby was finally delivered by cesarean section. When the meconium first appeared the heart tones were quite weak. I attempted to induce labor in this case since it was at full term at two different times with quinine, castor oil and solutions of pituitary but was unsuccessful. I then had consultation and a specialist suggested that I insert a bag and attempt to induce labor. This also was unsuccessful in starting contractions for more than a few hours. Finally a low cervical section was done the baby was born alive and the mother recovered well. The baby had a marked desquamation of the skin at the time of birth, large plaques of skin peeling off intact. The baby has gained and is doing fine at the present time. What I want to know is whether meconium could produce maceration of the skin or was some other factor the cause of this peculiar condition? Could you give me the chemistry of meconium and is it not unusual for a baby to pass meconium for ten days and still be alive? Kindly omit name. M D Washington

ANSWER—The passage of meconium in this case has no significance and was to be expected, because the baby presented by the breech and the membranes were ruptured. The expulsion of meconium in a breech presentation is not a cause for alarm, because it is almost always due to pressure on the fetal abdomen, which results in mechanical expulsion of the meconium. When meconium is passed in the presence of a cephalic

presentation, it usually signifies fetal distress. In such a case the fetal heart tones are nearly always irregular in rhythm or unusually rapid or slow. In cases in which the heart tones remain regular in the presence of meconium, there is generally no immediate danger to the child, but the fetal heart tones should be carefully controlled until the baby is born.

In cephalic presentations the expulsion of meconium is due to stimulation of the sympathetic nervous system, especially the celiac ganglion, which leads to excessive peristalsis of the intestine. This stimulation of the sympathetic nerves is due to an abnormal mixture of gases and hence it is a disturbance in the respiratory mechanism of the fetus. The sympathetic nervous system is stimulated by an abnormal gas mixture sooner than the vagus center. This explains why meconium usually is expelled before alterations in the heart tones appear.

Meconium may be found in a fetus from the fourth month on. It consists of epithelium from the intestinal tract, mucus, bile, bilirubin, fat, cholesterol crystals, lanugo hairs, vernix caseosa, skin epithelium and the digestive juices of the stomach, pancreas and intestine, but 80 per cent of meconium is water.

It is hardly likely that the meconium produced the extensive desquamation of the skin in this case, chiefly because most of the meconium was expelled directly from the anus through the cervix into the vagina. If most of the meconium had remained in the uterine cavity and had come into intimate contact with the baby's skin, it could have had deleterious effects on the skin. The desquamation is more likely due to the absence of liquor amni and to a mild infection. The latter was most likely present because of the long delay after the rupture of the membranes and because of the bag induction.

JUTE DERMATITIS

To the Editor—Is there such a thing as poisoning from the oil used in softening sisal in the manufacture of jute or even in the jute or sisal itself which would give what workmen in such plants call 'oil poisoning'? I have a patient who has had a reddened, scaly itching chronic, recurrent, pustular unibilicated dermatitis for more than a year. It cleared up with injections of boiled milk, but I should like to know if there is any connection with the oil or if it is mere coincidence. Please omit name.

M D Kentucky

ANSWER—Sisal or jute dermatitis is a fairly well known industrial disease entity. The action is attributable partly to the soaps, fish and mineral oils employed in the manipulation of the vegetable fiber and partly to the mechanical action of the fibers themselves. Also allergy may play some part in the causation of this condition. From an International Labor Office publication (1930), *Encyclopedia of Pathology, Hygiene and Social Welfare*, brochure 212, the following is taken:

'Skin affections, characterized by irritation of the skin, redness and swelling, dry eczema, papillary hypertrophy and inflammation, advancing even to suppuration, have been reported in people handling jute where the thread was impregnated with a solution of yellow soap, impure fish oil and mineral oil.'

"The coloring matters and oils handled in manipulating jute are the cause of the folliculitis observed, notably in India. The lesion is nonsuppurative in character brought on by mechanical obliteration of the orifice of the sebaceous glands by debris from the corneal layer, the exfoliation of which is obstructed by the presence of the oil on the skin. The accumulation of this debris is frequent among the natives, who do not use detergent soap sufficiently, water alone being insufficient in these cases."

The entry of mycotic organisms frequently prolongs the duration of this type of industrial dermatitis.

HYPERPYREXIA IN NEW BORN

To the Editor—I recently saw a baby 24 hours old with a rectal temperature of 109 F. The only other abnormality was the presence of many coarse rales in the bronchial tubes. Will you please explain hyperpyrexia in new born babies? Please omit name.

M D Iowa

ANSWER—The history of this case is unusual. A temperature of 109 F. in a new-born baby has not been frequently reported. The elevation of temperature occurred earlier than is usually observed. Generally the temperature in the so-called transitory fever of the new-born is from 100.5 to 102 F., though it may be higher. The fever is usually observed on the third or fourth day, and the earliest is usually at the end of the second, though it may not occur until the fifth day. It may last only a few hours or continue for two or three days. E. L. Holt observed that the highest temperature usually coincided with the time when the loss in weight was greatest. As a rule, fever disappears as the weight increases, though this is not invariably the case, because the temperature may return to normal without increase in weight and without increase in

the amount of water ingested. There are several explanations for this so-called transitory fever. Some have thought it due to intestinal infection or intoxication. It has been suggested that it might be due to fever-producing substances in the colostrum. It has been learned from experience with older infants that an insufficient supply of fluids may produce fever. Consequently it has been thought that most of the transitory fevers of the new-born period are thirst fevers, although it is possible that the febrile reactions may be due in part, at least, to the breaking down of the blood cells or other body proteins, giving rise to the so called protein fever. It should be remembered that the new-born baby's temperature regulating mechanism is characterized by extreme lability. An excessively hot bath, an overheated water bag or the application of external heat of any kind may cause a decided febrile reaction. Meningeal or intracranial hemorrhages or malformations of the brain may also cause high fever. Septic processes, especially localized umbilical infection, may cause temperature fluctuations, though one would hardly expect a febrile reaction from such a cause to occur as early as the first day of life.

Without more definite details it is not possible to interpret the coarse rales in the bronchial tubes, though it should be remembered that new-born and young infants may develop pneumonia as the result of aspiration of amniotic fluid during labor, or to the rare antenatal or postnatal pulmonary infections.

NUMBNESS OF FINGERS

To the Editor—In Queries and Minor Notes in THE JOURNAL May 25 page 1929 your reply states that numbness of the middle three fingers does not correspond to the distribution of the peripheral nerves. It is true that the numbness of the middle three fingers does not correspond to the distribution of any named peripheral nerve but it does correspond exactly to the distribution of the seventh cervical root according to figures 90 and 91 on pages 359 and 360 of the ninth edition of Surgical Applied Anatomy by Sir Frederick Treves revised by C. C. Choyce in 1934. Therefore it is possible that the pressure on the seventh cervical nerve by a cervical rib or something else may cause the numbness of the middle three fingers.

Council on Medical Education and Hospitals

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, March 2.

Hospitals Approved for Intern Training

St. Mary's Hospital Pueblo, Colo
St. Mary's Hospital Huntington W Va

Hospitals Approved for Residencies in Specialties

Employees Hospital of the Tennessee Coal Iron and Railroad Company
Fairfield Ala. Medicine and surgery
Maryland Tuberculosis Sanatorium, State Sanatorium Md Tuberculosis
Plymouth County Hospital South Hanson Mass Tuberculosis
Worcester State Hospital Worcester Mass Psychiatry
University Hospitals Columbia Mo Orthopedics
Hudson County Tuberculosis Hospital and Sanatorium Secaucus N J Tuberculosis
Municipal Sanatorium Otisville N Y Tuberculosis
St. Thomas Hospital Akron Ohio Surgery and mixed residencies
Youngstown Hospital Youngstown Ohio Mixed residencies
Willis C Campbell Clinic Memphis Tenn Orthopedics
Galveston State Psychopathic Hospital, Galveston Texas Psychiatry
Salt Lake General Hospital Salt Lake City Mixed residency
Norfolk Protestant Hospital Norfolk Va Medicine and surgery

Hospitals Approved for Additional Residencies

Garfield Memorial Hospital Washington D C Pathology
James M Jackson Memorial Hospital Miami Fla Mixed residencies
Charity Hospital New Orleans Orthopedics and pathology
Boston City Hospital Boston Ophthalmology-otolaryngology
Minneapolis General Hospital Minneapolis Psychiatry
Albany Hospital Albany N Y Tuberculosis
Long Island College Hospital Brooklyn Pathology
Lenox Hill Hospital New York City Pathology and neurology
Morrisania City Hospital New York City Obstetrics
Duke Hospital Durham N C Urology orthopedics and psychiatry
St. Luke's Hospital Cleveland Pathology
State University Hospital Oklahoma City Anesthesia and obstetrics
Presbyterian Hospital Philadelphia Mixed residency
Baroness Erlanger Hospital Chattanooga, Tenn Mixed residency

Book Notices

Hugh Owen Thomas A Personal Study By Frederick Watson Cloth Price \$4.25 Pp 94 with 8 illustrations New York & London Oxford University Press 1934

This little book contains interesting reading concerning one of the unique figures in medicine and surgery. It is a personal study of Hugh Owen Thomas by Frederick Watson, who also wrote the life of Sir Robert Jones, who was Hugh Owen Thomas's nephew. The author is well qualified to make the study. The book will be followed by a companion book on the principles and practice of Hugh Owen Thomas, written by Mr McCrae Aitken.

Born of a family of unqualified but highly respected "bone setters," Hugh Owen Thomas made a name that will probably live forever. Realizing the handicap of "unqualification," his father sent five sons—including the leading character of this book—to the Edinburgh Medical School. All five sons graduated in medicine and surgery and proceeded to London, following which each in turn became the assistant of Dr Owen Roberts. The Thomas family lived generation after generation in the district of Wales least accessible to modern progress and ideas. It was the country of the druids, whose descendants the bards, still expressed the sentiments of the people. The history of the Anglesea bone-setters provides an impressive picture of a family devoted to the art of healing throughout eight consecutive generations and inspired largely by a sense of divine guidance and a faith in an inherited faculty for handling dislocations. As well-to-do yeoman farmers, the Thomases could afford to attend their neighbors without fee. The paternal great-grandfather of Hugh Owen Thomas was one of the most celebrated and skilful of this family of bonesetters. His name was Evan Thomas. There is evidence of the important place of the family in North Wales, whose descendants a generation after the death of Evan Thomas included no less than twenty-one doctors or bone setters of both sexes. Evan Thomas was until his death overwhelmed by patients drawn from the seafaring communities and from the docks. His immense general practice provided a greater variety and number of cases than any other in the world. It was estimated that he saw between thirty and sixty patients a day. Doubtless a percentage of these came to his son Hugh Owen Thomas, but the bulk of his work consisted of the medical supervision of shipwrights, iron workers, boilermakers, seamen, dock gatemens and industrial concerns. This varied field served him in place of a hospital appointment, which an outraged medical community in Liverpool resolutely refused him to the end of his life.

Physically Thomas was a diminutive man, and intellectually not a little alarming to the conventional environment of a Welsh home. But of his high character and courage there could never have been any question. And even his eccentricities were not without a tender and romantic glamor. He wore a peaked cap, to protect an injured eye, and smoked cigarets continually. Thomas was a man of indomitable courage and a fine sense of a physician's moral duty. During his engagement to the beautiful Elizabeth the great cholera epidemic broke out in Liverpool. Without a moment's hesitation he flung himself into the heart of the ghastly slums where it was raging. Night and day he labored for the unfortunate uncared for class on whom his great reputation was destined to be established. His escape from infection was miraculous, and the explanation given by Thomas himself was the precaution he took of smoking. Thomas was a tremendous worker in a sense and to a degree quite outside the capacities of ordinary men. He did not work for money or to secure success. He worked because he loved his calling and found the greatest and most enduring happiness in it. He was obsessed by a sleepless search for truth. It drove him on from dawn to dusk. To most men the consolations for work lie in prestige, money or power. To Thomas the only reward was knowledge through progress. His watchword 'On' describes his physical and spiritual impulses. The sacrifice of everything for knowledge made him so eager and determined in argument that he created more enemies at the end of his pen than many men could have done at the point of

a sword. Nor was he a man who could relax. Even in his occasional hours of leisure late at night he was occupied with his lathes or practicing the flute. He was considered an original, entrancing, heroic husband. If one should attempt to analyze Thomas's special aptitudes, one would say that they consisted in an original mind not in the least tainted with reverence for authority as authority, whatever its source.

Dr John Ridlon said "During my fourteen days with Thomas I saw more injured and diseased shoulders than ever before or since. Why? Because he was the surgeon for twenty-eight labor organizations along the Liverpool docks." Ridlon's opening statement to Thomas was "Mr Thomas, I have read your book on the hip, knee and ankle and I have come three thousand miles to find out whether I am a fool or you a liar." Ridlon has said that "the greatest thing Robert Jones ever did was to make the main principles of Thomas acceptable to the profession."

Thomas realized that if a working man does not miss more than a few hours from his work because of an injury, it never occurs to him to choose compensation and idleness instead of the full pay that his work brings him. Treated in their own home, most workmen are anxious to get back to their work. Cared for in the sunny ward of a clean hospital by an attractive nurse it is quite different. Why worry about getting back to work? Hugh Owen Thomas had his home, office and brace shop at 11 Nelson street, Liverpool, which is a byword in orthopedic surgery and considered the birthplace of modern orthopedics in Great Britain.

The book contains several interesting illustrations, especially the one showing Thomas wearing a cap and smoking a cigaret while reducing a dislocation of the shoulder, with the future Sir Robert Jones assisting.

Die ansteckenden Krankheiten ihre Epidemiologie Bekämpfung und spezifische Therapie Herausgegeben von Prof. Dr. med. et phil. Max Gundel Institut Robert Koch Berlin. Unter Mitarbeit von E. Boecker et al. Paper Price 35 marks Pp 641 with 25 illustrations Leipzig Georg Thieme 1935

This book is written by twenty-two German medical scientists who are especially well qualified for their respective tasks by reason of training and function. The main part is devoted to the control and treatment of the individual infectious diseases, which include bacterial spirochetal and protozoan infections as well as the virus diseases of unknown etiology, fungous diseases and the diseases caused by worms. There are also much shorter parts dealing with governmental regulations for communicable diseases, the general principles of infectious pathogenesis and immunity, the production and use of antisera and vaccines, serum disease, the examination of infectious materials and the role of disinfection and sterilization. The purpose of the book is to tell physicians in private as well as official positions what they should know about communicable diseases, their causes, modes of spreading, diagnosis, prevention and treatment in order to fulfil adequately their responsibilities in such matters. The book meets this purpose well. It gives in concise and well balanced form the best scientific and practical knowledge about communicable diseases of the day.

A Text Book on Pharmacognosy By George Edward Trease B. Pharm. Ph.C. Lecturer on Pharmacognosy in the University College of Nottingham. With contributions by H. H. Barber B.Sc. Ph.D. F.I.C. W. H. Heading B.Sc. Ph.C. A.I.C. H. M. Hirst M.P.S. and A. H. Ware Ph.C. Cloth Price \$6 Pp 653 with 187 illustrations Baltimore William Wood & Company 1935

This book aims to cover the requirements for examinations in pharmacognosy in most English speaking countries. It is of interest especially to pharmacists. It has, however, a cultural atmosphere, which related sciences and medicine must admire. In part I, chapter I gives a short historical introduction and shows the importance pharmacognosy has had in world affairs. Chapter II gives some interesting and instructive facts about the cultivation of medicinal plants in England. Chapter III discusses enzymes succinctly. Chapter IV gives a brief outline of vitamins. In chapter V the subject of hormones is equally brief but down to date. Chapter VII deals with the process of collection, drying and storage of plants. Chapter VIII discusses historically London commerce in crude drugs. Chapter

IX deals with plant principles and their extraction Chapter X gives tests for plant phenols as an aid in drug identification, and chapter XI is concerned with the microscope as an aid to drug identification Chapter XII deals with ultraviolet rays as an aid to drug identification Part II (chapters XIII-XX) deals with drugs of vegetable origin and comprises the greater part of the book Classification and its variations by different authorities is discussed Part III deals with drugs of animal origin and includes hirudo, cantharis, mei, cerae, coccus, lacca, os sepiae, oleum morrhuae, cetaceum, adeps sebum, adeps lanae, gelatinum, moschus and extractum felis bovis A glossary of Latin terms is appended While the book is primarily intended for students of pharmacy, it is of a sufficiently scholarly nature to be valuable to those medical men who wish a brief, readable, accurate book on pharmacognosy Such subjects, however, as enzymes vitamins, hormones, ergot and digitalis are treated in too brief a fashion to be of value to those wishing more than factual statements Practically no references to original work are given

Handbuch der experimentellen Pharmakologie Begründet von A. Heffter Ergänzungswerk Herausgegeben von W. Heubner Professor der Pharmakologie an der Universität Berlin und J. Schüller Professor der Pharmakologie an der Universität Köln Band I. Enthaltend Beiträge von H. H. Meyer und L. Lendle Paper Price 32 marks Pp 265 with 37 illustrations Berlin Julius Springer 1935

The editors plan to publish a new series of volumes on experimental pharmacology, supplementing Heffter's handbuch This, the first supplemental volume, is concerned with the digitalis bodies and related glucosides and is written by Lendle of Leipzig A ten page introduction on the nature and objects of experimental pharmacology is written by the dean of European pharmacologists Hans Horst Meyer of Vienna Part of Heffter's first volume appeared in 1919, and the final volume has not yet appeared The chapter on digitalis, written by Straub of Munich, contained the literature up to 1914, but it was not published until later From the subsequent twenty years, Lendle quotes about 1400 authors and perhaps 3000 or more articles This massive, nebulous, cumulus cloud of research fog must be condensed and refined before it is of much value to the ordinary doctor and also to many who are not ordinary This refining process, however, is not the task of the immediate editor His work is to collect and present the data in a form useful to other research workers, who will do the refining The preparation of the work has required unlimited patience and perseverance, and it is well done It is a source book a work not only pro patria but pro mundo The work includes every phase of the digitalis problem, including the most recent chemistry, standardization, the action of the related glucosides, conditions modifying its activity, actions on the various tissues or extracardial actions, absorption, fate and elimination One may find how digitalis action is influenced by acetylcholine histamine the barometer fever or high altitude, and the effective doses for various animals The volume is primarily of interest to research workers who must have it, but physicians interested in the basic facts of pharmacology and the source of therapeutic procedures in the use of digitalis will find it a mine of information

Nutrition By Margaret S. Chaney Ph.D. Professor of Home Economics Connecticut College and Margaret Ahlborn M.S. Professor of Food Economics and Nutrition Kansas State College of Agriculture and Applied Science Cloth. Price \$3 Pp 436 with 55 illustrations Boston Houghton Mifflin Company 1934

The usefulness of this excellent textbook on nutrition, planned for home economics courses in colleges and normal schools, extends to all interested in the relation of nutrition to health, from which point of view the book has been developed The subject matter is interestingly and simply presented requiring only a minimum background of organic chemistry and physiology for thorough understanding The interest of the reader is sustained and stimulated throughout The role of each principal food essential in good nutrition is successively discussed in separate chapters There are chapters devoted to food energy, basal metabolism protein minerals vitamins, hygiene of the digestive tract nutrition during the reproductive period optimal nutrition during infancy and childhood and the selection of an adequate dietary Suitable references are listed at the end of each chapter The appendix including the more important

useful data, is particularly comprehensive and practical The methods of animal experimentation applicable to vitamin testing are outlined The book splendidly prepares the adult to care intelligently for his own nutritional needs as well as those of the entire family group A better understanding of nutrition and a better state of nutrition should result from the publication of this exceptional work

Thrombose und Embolie Kritische Betrachtungen und Untersuchungen zur Frage der Thrombose und Embolie unter besonderer Berücksichtigung der sogenannten "bilden Fernthrombose" und tödlichen Lungenembolie. Von Dr. med. Rudolf Gelseandörfer Assistentarzt der Chir. Univ. Klinik Breslau Mit einem Geleitwort von Prof. Dr. R. Stüch. Boards Price 9 marks Pp 159 Leipzig Johann Ambrosius Barth 1935

This monograph embodies the results of a critical consideration of the thrombosis embolism question as discussed in recent German literature, more particularly progressive bland or aseptic thrombosis and pulmonary embolism The author discusses all aspects of the supposed increase in fatal pulmonary embolism some years after the war When all the factors concerned are considered and analyzed, especially the ages of the patients in the various statistics of thrombosis and embolism, the conclusion seems warranted that at the most the alleged increase is small indeed, if there has been any at all There are chapters on the relations between the blood current, the blood chemistry and the endothelium in thrombosis, on the diagnosis and treatment of thrombosis, and of massive pulmonary embolism as well as their prophylaxis The monograph will interest those who wish to follow the growth of a better understanding of the problems of thrombosis and embolism

Diseases of the Skin By Richard L. Sutton M.D. Sc.D. LL.D. Professor of Dermatology University of Kansas School of Medicine and Richard L. Sutton Jr. A.M. M.D. L.R.C.P. Assistant in Dermatology University of Kansas School of Medicine Ninth edition Cloth Price \$12.50 Pp 1433 with 1,321 illustrations St. Louis C.V. Mosby Company 1935

In this edition Sutton, with the aid of his son, has followed the general plan of the previous editions The excellence of the work is revealed by a careful examination of its contents Twenty-eight cutaneous entities not included in the previous editions are described Although many of the descriptions of conditions in the text are brief, the information is ample to give a good idea of the basic points necessary to identify the entity and there is a profuse number of excellent reproductions of photographs to aid in the visualization of the disease There are also numerous excellent photomicrographs to amplify many of the histologic descriptions presented Each description is followed by a list of references and the authors have made a sincere effort to make this list complete, thus making it possible for one desiring more detailed information on a particular condition to have pertinent references at hand

Kønshormonerne Betydning for fysiologiske og patologiske Tilstande i Corpus Mammæ En klinisk og eksperimentel Studie Af E. Dahl Iversen Dr. med. To Forelæsninger udarbejdet til en Konkurrence om et Professorat i Kirurgi ved Københavns Universitet. [Significance of sex hormones for physiology and pathology of breast Clinical and experimental study] Paper Pp 55 with 22 illustrations Copenhagen J. Jørgensen & Co 1934

Here are two lectures prepared for and delivered in a competition for a professorship in surgery at the University of Copenhagen The sex hormones of the hypophysis and ovary are discussed competently in relation to physiologic and pathologic conditions of the mammary gland Earlier work and the author's own experiments on the action of the ovarian hormone on the mamma are described and the resulting changes in animals compared with conditions in so called chronic cystic human mastitis Whether cancer develops more frequently in women with cystic mastitis than under other conditions cannot be answered on the basis of the information obtained, according to the author

Mouth Infection Clinical Histories By Oliver T. Osborne M.A. M.D. F.A.C.P. Cloth Price \$2 Pp 119 New Haven Conn. The Author 1934

Dr. Osborne has been for a good many years convinced that infections of the teeth and gums are of the greatest importance in relationship to various general conditions affecting the human body This is essentially the same conception as that of focal infection. The present book is planned to emphasize his point

of view and to support it by the presentation of a considerable number of case reports. These are presented in two or three lines each and, frankly, because of this simple presentation are not especially convincing. The second portion of the book concerns tonsillar infection, and the third portion Vincent's infection or trench mouth. There are also brief essays on the adenoids, the tongue and the tooth brush. The volume is suggestive and exceedingly well written. Even discounting its overemphasis on the mouth as a source of general danger to the body, its value cannot be gainsaid.

Medicolegal

Malpractice Sponge Left in Pelvic Cavity—The physician-defendant operated to remove a tumor from the plaintiff's pelvic cavity. He walled off the bowels by "retractor pads" on which were sewed pieces of tape about 14 inches long, the ends of which hung outside the patient's body, attached to surgical instruments. To arrest capillary hemorrhage in the operative area he "wadded up" other gauze pads and placed them against the bleeding tissue, but he "wadded up" with the gauze the tape attached to the pads or sponges so used, so that the ends did not protrude outside the body. The patient had been on the operating table about one hour and thirty-five minutes when the anesthetist reported that the patient was showing signs of shock and advised that the operation be completed as soon as possible. The peritoneum had already been completely sutured when a nurse reported that one sponge was missing. Immediately the peritoneal sutures were removed and for about five minutes a search was made for the missing sponge, but it could not be found. About ten weeks after the operation the patient passed through her rectum a sponge similar to those used to arrest bleeding. She sued her physician, and a judgment was rendered in her favor. Her physician then appealed to the district court of appeals, fourth district, California.

The appellate court called attention to the fact that, in the absence of an express contract, a physician does not warrant a cure. He represents only that he has the ordinary training and skill possessed by physicians practicing in the same or similar communities and that he will employ such training, skill and care in the treatment of his patient. A physician who holds himself out as a specialist in the treatment of a certain organ, injury or disease is bound to bring to the aid of a patient employing him that degree of skill and knowledge which is ordinarily possessed by those who devote special study and attention to that particular organ, injury or disease in the same general locality, having regard to the state of scientific knowledge at the time. The evidence, said the appellate court, indicates that the physician defendant was a specialist in abdominal operations.

On behalf of the patient-plaintiff, a physician testified that good practice in the locality where the operation was done required a physician to retain manual control of sponges used to arrest bleeding in operations such as the one here involved or else to bring the end of a tape attached to each sponge to the outside of the patient's body and to have it attached there to a metal ring or a surgical instrument. It is admitted, said the court, that the defendant did not use this method in operating; that of itself is sufficient to support the trial court's finding of negligence. It is evidence that the physician-defendant did not use the care and skill used by physicians performing similar operations in the same or similar communities. But the number of witnesses who testified for the defendant exceeded the number who testified for the plaintiff and the defendant insisted that the evidence as to the correctness of the methods employed by him so greatly preponderated in his favor as to overcome completely the evidence offered on this question on behalf of the plaintiff. The district court of appeals pointed out, however, that a case cannot be decided in an appellate court on the numerical strength of witnesses. Conflicts of evidence are settled in the trial court and a judgment cannot be reversed where there is competent and material evidence in the record to support it.

The appellate court was not impressed by a suggestion made on behalf of the plaintiff that her evidence disclosed numerous

things that could have been done, but that were not done, to relieve the operative shock and to permit a prolongation of the search for the lost sponge until it was found and removed. The physician-defendant was confronted with a great emergency. His patient was in a very serious condition, her life was in danger, and the element of time was most important. Under such circumstances, the physician had to rely on his own skill, knowledge and best judgment in choosing the course to pursue. Nevertheless, the judgment of the trial court in favor of the patient-plaintiff was supported by the evidence concerning the manner in which the physician-defendant used sponges to arrest bleeding, and the judgment was accordingly affirmed.—*McLeman v Holder (Calif.)*, 36 P (2d) 448.

Evidence Roentgenograms as Public Records, Admissibility—In September 1929 the defendant insurance company issued a policy of insurance on the life of Mattie E. Suggs. She died, April 13, 1930, in the state tuberculosis sanatorium at Clinton, Okla. The insurer denied liability, and her beneficiary brought suit. From a judgment for the beneficiary, the insurer appealed to the Supreme Court of Oklahoma.

Because of the Oklahoma statute relating to privileged communications, the trial court refused to permit a physician who had attended the insured to testify that he had treated her for tuberculosis in July, prior to her application for insurance. In that application she had denied that she had ever had tuberculosis and asserted that she had received no medical attention within the five years preceding it. The refusal of the trial court to admit this testimony, said the Supreme Court, constituted reversible error. The insured, in her application for insurance, expressly waived all provisions of law prohibiting a physician from disclosing in court information acquired in examining or attending his patient. This waiver was binding on the beneficiary of the deceased, the plaintiff in this case, and the testimony of this physician should have been admitted.

In the course of the trial, the insurance company offered in evidence the record and history of the insured as made and kept by the nursing bureau of the Oklahoma City health department. The record included roentgenograms of the lungs, made before the deceased applied for insurance. To prove its authenticity the superintendent of the nursing bureau testified that it was a public record. She testified, however, that the record was not made by her but by other nurses in the department. The insurance company contended that the record, as a public record, was admissible. The trial court, however, refused to admit it. This refusal, the Supreme Court held, was proper. The preliminary facts necessary to be shown in order to admit roentgenograms in evidence had already been stated by the court, the court said, in *Barllesville Zinc Co v Fisher*, 60 Okla 139, 159 P 476.

The admission of x-ray plates in evidence rests fundamentally on the theory that they are the pictorial communication of a qualified witness who uses this method of conveying to the jury a reproduction of the object of which he is testifying, this being true the x-ray plates must be made a part of some qualified witness testimony and the witness should qualify himself by showing that the process is known to himself to give correct representations and that it is a true representation of such object.

No such showing was made with respect to the roentgenograms proffered in this case.

For the reasons stated the judgment of the trial court in favor of the beneficiary was reversed and the cause was remanded for a new trial.—*National Life & Accident Ins Co v Roberson (Okla.)*, 36 P (2d) 479.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Histogenesis of Lymphosarcomatosis—Ehrlich and Gerber found that studies of material from eighteen cases of lymphosarcomatosis revealed varied histologic pictures, which could be grouped into three main types on the basis of the morphologic characteristics of the predominating cell type in each case. There were found, first, cases in which large, pale cells in reticular arrangement predominated. Then there occurred a group composed of mixed cells, partly reticular, as in the former group and partly free. The morphology of these free cells resembled that of immature large lymphocytic cells. Finally, cases were encountered in which the lymphosarcomatous tissues were composed predominantly of free cells, either of the immature or mature lymphocytic type. These three types were termed, for descriptive purposes, reticular, intermediate and lymphocytic, respectively. These types were found to correspond in their essential morphologic features to the immature, intermediate and mature cells resulting from normal differentiation of the cytoplasmic reticulum along lymphopoietic lines. This similarity indicated that the histogenesis of this disease consists of progressive lymphopoietic differentiation of the cytoplasmic reticulum. This process is confined chiefly to the cytoplasmic reticulum of lymphatic tissues. Lymphopoiesis, as it occurs in lymphosarcomatosis, manifests blastomatous characteristics. These are indicated by the unrestricted growth of the tumor masses and the atypism of the cells. Lymphosarcomatosis arises in a region of lymph nodes, from which it extends to other regions of lymphatic tissue and other organs in progressive fashion. This spread occurs by direct local extension and by metastasis by way of the lymphatics and the blood stream. In addition, there occurs autochthonous formation of lymphosarcomatous foci in many centers of lymphatic tissue. This autochthonous origin is evi-

dent in partially involved nodes, in which intermediate stages in the formation of these foci from local reticulum cells may be observed, and in the diffuse involvement of the malpighian follicles of the spleen in two cases. As a result of these modes of spread, many cases of lymphosarcomatosis show, in their late stages, a widespread involvement of the lymphatic tissues (with the exception of the spleen) and of other organs. The origin of lymphosarcomatosis simultaneously in various lymph nodes in one region, the autochthonous mode of spread and the tendency toward restriction to one type of tissue separate this disease from the true sarcomas. Lymphosarcomatosis bears certain resemblances to lymphadenosis, such as identical histogenesis, restriction to lymphatic tissue and systematization. Nevertheless, the focal origin of the former, the more aggressive character of its growth, the focal involvement of lymph nodes and the limited systematization serve to characterize lymphosarcomatosis as a blastomatous disease of lymphatic tissue, in contrast to the hyperplastic character of lymphadenosis. From an oncologic point of view, lymphosarcomatosis may be classified as a blastomatous disease in the group of hemoblastoses.

Studies of Correlated Human and Bovine Brucelliasis—Stone and Bogen show that the ingestion of raw milk obtained from cows infected with contagious abortion and showing positive tests for agglutinins to *Brucella abortus* in their blood is responsible for the development of similar agglutinins in the blood of some consumers. This has been found to occur in about 8 per cent of those continuously exposed to the ingestion of heavily infected raw milk but varies with the duration of exposure, the amount of infection in the herd and the amount of the raw milk so consumed. No particular sex or age susceptibility to this infection has been found. No effect of tuberculosis or other disease on the development of such agglutinins is apparent, except insofar as they affect the amount of exposure to the infected milk. The development of such agglutinins has not been found to exercise any marked effect on the course of the tuberculosis. More than half of the patients developing agglutinins to *Brucella abortus* give no other manifestation of the infection and, therefore, come well within the groups described as subclinical asymptomatic or purely serologic brucelliasis. About one eleventh of them manifest clinical symptoms warranting a diagnosis of undulant fever, and an additional group present other symptoms that might be attributed to the same cause. The disease manifestations are, however, comparatively mild, conforming, therefore, to the bovine type of infection, as described by Theobald Smith, rather than to the more virulent types that are frequently described from caprine or porcine sources. It constitutes, however, a definite disease entity and cannot be disregarded.

Virulence Tests for Typhoid Bacilli—Norton and Dingle place particular emphasis on the measurement of the protective action of the antiserums in an attempt to determine whether there is a correlation of such activity with some known and easily determined property of the antiserums and whether this property may be correlated with antigenic components of the organisms being studied. Methods for determination of virulence of typhoid bacilli and for measurement of protective action of antityphoid serums are presented, together with preliminary data obtained by these methods. Intracerebral injection into mice is recommended for measurement of the relative virulence of strains of the typhoid bacillus. This method of injection has given more satisfactory results than the intraperitoneal route. Intracerebral injection of organisms combined with intraperitoneal injection of antiserums is suggested as a method for measuring the protective value of these serums against typhoid bacilli. The data so far obtained do not justify definite conclusions but serve to indicate the feasibility of the technique and a possible correlation between virulence, H and O agglutinins and protective activity of the antityphoid serums.

Antigenic Properties of Defatted Tubercle Bacilli—Boissevain tested the activity of decomposition products of the tubercle bacillus in producing hypersensitiveness in guinea-pigs to find the exact stage at which this activity disappears. Varying quantities of all the antigens examined were injected into a series of guinea-pigs to determine the minimal amount necessary to cause the appearance of hypersensitiveness to tuberculin. After three weeks the guinea-pigs were tested with different dilutions of water-soluble tubercle protein to determine the degree of hypersensitiveness that had been established. It was found that water-soluble protein obtained from ground bacilli, from hydrolyzed bacilli or from filtered culture mediums, all have the same tuberculin activity. Doses of from 1 to 40 mg of defatted tubercle bacilli make guinea-pigs hypersensitive to 0.1 cc. of a 0.01 per cent solution of tuberculoprotein. The same doses of the insoluble residue obtained by grinding make guinea-pigs hypersensitive to 0.1 cc. of a 1 per cent solution. It was not possible to make guinea-pigs hypersensitive to a solution of 1 per cent tuberculoprotein by the injection of from 10 to 100 mg of any water-soluble or alkali-soluble protein or peptone derived from the tubercle bacillus.

Intracutaneous (Mantoux) Tuberculin Reaction.—Paretzky found that a comparison of numerically almost equal groups of positive and negative tuberculin reactors who belonged to the same families showed that both diagnosis and prognosis were considerably more unfavorable for the negative group. The "dosage" of the infection and the length of exposure were found to be factors of great importance which had influenced the developments among the negative reactors who later showed evidences of tuberculous disease. The negative reactors who remained nontuberculous were either removed from the source of the infection or had acquired a positive tuberculin reaction. In accordance with these observations the author practices in his work, as a prophylactic measure, early interruption of exposure as much as possible, in all cases (with all kinds of con-

tacts, positive and negative) and especially in cases of massive infection. Special attention is paid to negative reactors if for some reason they remain exposed to infection, they are frequently reexamined and are otherwise closely watched.

Compound Solution of Iodine in Acute Parotitis—Leithauser and Cantor administered compound solution of iodine orally in ten cases of acute secondary parotitis. The drug is well tolerated and may be given in large and repeated doses for days. In the more serious cases compound solution of iodine was also administered by hypodermoclysis in saline solution. Three cases followed spinal anesthesia, two followed ether, two followed gas, and one followed a local anesthetic. The fact that three cases followed spinal and one local anesthesia tends to disprove the contention that pressure over Stensen's duct is responsible for this complication. In every case in which a culture was made from Stensen's duct, either a *Staphylococcus aureus* or *albus* was recovered, except one which was a *diplococcus*. One case was bilateral, *Staphylococcus aureus* was recovered from the left Stensen's duct and *Staphylococcus albus* from the right. There were no signs or symptoms of iodism in any of the cases treated. Two cases went to abscess formation. There were no deaths.

Operability of Carcinoma of Stomach—Hunt states that, even though the diagnosis of carcinoma of the stomach has reached a high degree of accuracy with roentgen examination, the operability of malignant lesions remains very low. In the author's 149 patients operated on during the last ten years, the operability in terms of resection was 36.2 per cent of the patients explored. The operability has varied but slightly. The operability in terms of the curative procedure of resection or partial gastrectomy in patients with cancer of the stomach has varied from 48 to 33 per cent. Operability in terms of resection has in recent years increased materially in the hands of those particularly interested in the surgical treatment of carcinoma of the stomach. The employment of methods in recent years for the rehabilitation of patients with carcinoma of the stomach previous to surgical exploration has contributed to reduction of the risk of gastric resection. Repeated gastric lavage for gastric retention, the intensive administration of dextrose and of physiologic solution of sodium chloride to combat dehydration and restore the normal balance in the chemistry of the blood and the preoperative treatment of secondary anemia by blood transfusion are most important in the improvement of the general condition of the patient before operation and in the reduction of the risk of surgical procedure. Partial gastrectomy for malignant disease can be accomplished within a mortality rate of 10 per cent if not extended beyond what may reasonably be accepted as operable lesions. Total removal of the stomach with anastomosis has been successfully accomplished in a number of instances. The mortality rate of the procedure will of necessity always be high, but the risk at times may be justifiable. Total removal of the stomach for cancer is justified only in those cases in which the stomach

can be sufficiently mobilized to provide access to the esophagus so that an accurate anastomosis can be made between the esophagus and the jejunum. Palliative surgical procedures are seldom warranted when clinical manifestations of metastasis or inoperability exist. On exploration the determination of inoperability should preclude palliative operations unless the reasonably anticipated palliation justifies the risk. Prognosis following gastric resection depends on whether or not the resection has been sufficiently wide to include not only the primary lesion but any and all involved regional lymph nodes and on whether undetectable metastatic lesions are present elsewhere at the time of operation. Only through investigation of the significance of digestive symptoms in the adult patient by competent roentgen examination may the future operability of carcinoma of the stomach be increased. An opportunity exists to increase the curability of this disease, and it is probable that this will come about through its earlier recognition and not through extension of operability through higher gastric resection or total gastrectomy. There is a justifiable mortality for gastric resection for malignant disease which will vary with the individual surgeon, but as a general working rule this should seldom exceed the percentage prospect of cure.

Sarcoma of the Stomach—Pack and McNeer report nine cases of sarcoma of the stomach, consisting of four cases of myosarcoma, three of primary gastric lymphosarcoma and two of generalized lymphosarcomatosis with secondary involvement of the stomach. Sarcomas comprise 1 per cent of all gastric tumors. The sexes are equally involved. The average age of the patients is 46 years. Some of the tumors are symptomless. The greater number of patients present an upper abdominal tumor without definite gastric distress. Obstructive symptoms are infrequent. Pain occurs only in the presence of ulceration of the mucosa. The average duration of symptoms is nine and a half months. Sarcomas of the stomach are difficult to distinguish from carcinomas by roentgen studies, although horizontal filling defects and the persistence of gastric peristalsis in the presence of a definite lesion are suggestive. Partial gastrectomy is the procedure of choice for the localized tumors and is especially successful in exogastric sarcomas. The gastric lymphosarcomas are extremely radiosensitive and respond favorably to carefully planned radiation therapy.

Endocardial Tuberculosis—Baker states that endocardial tuberculosis is most frequently encountered at necropsy as a part of generalized miliary or disseminated tuberculosis. Scattered tubercles ranging from microscopic size to a diameter of 3 or 4 mm may occur in any part of the endocardium including the valves. They probably arise by implantation through the coronary arteries and directly from the blood of the heart. Rarely, they may be polypoid or pedunculated. Endocardial tuberculosis may also develop from the extension inward of pericardial and myocardial caseous masses, which may ulcerate and produce generalized tuberculosis. With staining for elastic tissue it can be shown that a myocardial tuberculous process bulging into the cavity of the heart but apparently covered with a smooth endocardial surface is in some cases really invading the endocardium. Tuberculous endocarditis as a diffuse process, somewhat analogous to rheumatic and pyogenic endocarditis, has no especial affinity for the line of closure of the valves and does not produce thrombotic vegetations. Endocardial tuberculosis may interfere with cardiac function in the rare instances in which caseous nodules involve the valves. Sclerosis of the endocardium and healed fibrous or calcified valvular lesions noted at necropsy were not shown to be due to the toxic action of a tuberculous process elsewhere in the body.

Histologic Studies on Spleen in Leukemia—Jaffe observed that in cases of leukemia the trabeculae of the spleen and the inner layer of the capsule are often involved by the leukemic process. In the larger trabeculae the leukemic tissue develops underneath the endothelium of the veins and, less frequently, in the adventitia of the arteries. In the smaller trabeculae the peripheral portions are gradually incorporated into the pulp, and nests of leukemic cells appear also in the center of the trabeculae. The cells in the center seem to originate locally from the fibrocytes. The changes have been observed in cases of acute stem cell leukemia, acute, subacute and chronic myelosis, acute and chronic lymphadenosis, monocytic leukemia and giant cell leukemia.

Osteogenesis—In his experiments on dogs, Bisgard found no new bone in the periosteal beds which had been treated thoroughly with Zenker's solution. Regeneration progressed normally from the periosteum when only the ends of the rib were treated with the solution, but there was definite retardation of absorption of old bone and of proliferation of new bone at the ends of the costal stumps. Transplanted treated costal segments had the appearance of encapsulated foreign bodies. They were entirely necrotic and formed no new bone but were considerably invaded by granulation tissue. In contrast, the untreated transplants, also necrotic, were extensively invaded by granulation tissue, were rapidly undergoing absorption and had given rise to some new bone. Much more new bone was present in the grafts covered with periosteum and on the cortical surfaces, which presumably had a covering of periosteum.

Epilepsy Secondary to Head Injury—A statistical study of cases of head injury reveals a wide discrepancy in the percentage of incidence of generalized epilepsy following trauma of the head. Glaser and Shafer observed that the most likely incidence is in the neighborhood of 2.5 per cent in the cases

of more severe head injury. Epilepsy does not develop after minor, but follows only severe, head injury and generally occurs only in cases in which there has been fracture of the skull. Generalized epilepsy may develop within the first ten days after head injury, provided the injury is of excessive severity. Post-traumatic epilepsy occurs most frequently from six months to two years after the injury, less frequently from two to seven years afterward and infrequently from seven to twenty years afterward. In attributing the epilepsy to trauma, all extraneous factors must be ruled out, particularly a history of convulsions prior to the trauma. Thorough physical and neurologic examinations should be made in order to establish that there is no organic, physical or neurologic disease and no mental condition other than the effects of the trauma causing the convulsions. In cases in which the first convulsion occurs at the time of the injury, a detailed history is necessary to make certain that the injury did not happen because of the onset of an attack of idiopathic epilepsy. Convulsive seizures developing in the first six months after minor head injuries should be considered psychoneurotic in origin, and every effort should be made to rule out such an etiology before the condition is diagnosed as true epilepsy. The authors know of no method of preventing the occurrence of generalized epilepsy following head trauma other than the utilization of the accepted methods of treatment of the original injury. Unless there is some special contraindication, they believe that encephalograms should be made in every case of posttraumatic epilepsy, both because they may have definite therapeutic value and because they may give further information of marked value in outlining advisable steps for treatment, in some cases they have shown evidence that open operation should be performed.

Chronic Ulcerative Colitis with Associated Carcinoma—Bargen and Dixon discuss twenty-five cases of carcinoma and two of lymphosarcoma proved at pathologic examination, in which the tumor developed in the course of severe chronic ulcerative colitis. The ages of the patients at the time of discovery of the carcinoma ranged from 21 to 69 years. Many of the younger patients had presented clinical and pathologic evidence of colitis for years. A sudden change of symptoms with unusual bleeding and local pain in patients who had been under repeated observation was considered to be indicative of the onset of carcinoma. For localized relatively early carcinoma of grades 1 and 2, in cases in which colitis is under fair control, radical extirpation of the diseased colon with the carcinoma offers the patient a good chance of recovery. In two cases polypoid excrescences in the rectum were fulgurated when the colitis was under control, and this treatment alone has been adequate so far, since the small carcinomas have not recurred. This suggests the importance of prompt proctoscopic observation with any change in symptoms and the importance of grading specimens removed for biopsy. In rapidly developing carcinoma among younger patients, it is more likely that the disease will be of the fulminating type and the carcinoma multiple and of a high grade of malignancy. An attempt to resect the growth locally when active or even quiescent colitis is present seems futile. It seems best to resect the entire section of the colon involved by colitis and containing one or more carcinomas. The authors believe that it is more than accidental that their five surviving patients had adequate treatment with specific antibody solution (concentrated serum) or vaccine prepared from the diplostreptococci of chronic ulcerative colitis, or both, prior to any attempted surgical procedure and that in each case the active stage of colitis was under control when surgical intervention was undertaken. Contrasted with this, only seven of the twenty-two patients who died were given serum or vaccine, and only three of them to the point of control of symptoms. In these three cases as healing took place the factor responsible for the healing lost control and the mucosa grew wildly as new hyperplastic tissue.

Treatment of Ragweed Hay Fever with Ultrafiltered Extract—Spain and Sammis made an attempt to determine clinically the value of ultrafiltered ragweed extract in the treatment of ragweed hay fever patients. In nineteen ragweed hay fever cases the comparisons, by the intracutaneous test, of the activity of residue and filtrate dilutions with the dilutions of the standard extracts as controls yielded results similar to those previously reported. The residue solutions showed a degree of activity quite comparable with those of the standard dilutions, while the filtrate was active only in its most concentrated or in its slightly diluted (1:5) form. From the results obtained in their series of nineteen cases it would seem that on ultrafiltration of the ragweed pollen extract the immunizing and constitutional producing capacity is retained in the residue fraction. Further study of its use in hay fever is being made.

Allergic Factor in Recurrent Paroxysmal Headaches—Vaughan states that true migraine is often due to food allergy. Upward of 70 per cent of recurrent paroxysmal headaches without organic pathologic conditions are associated with allergy. At least 7 per cent of a homogeneous community were found to have suffered at one time or another from recurrent headaches due to specific food idiosyncrasy. Such headaches appear to be more frequent in allergic persons than in the population at large. Factors that appear to influence results obtained in the treatment of allergic migraine are the period of supervision, the cooperation of the patient, the occurrence of headaches with the catamenia and a proper utilization of the available diagnostic measures (skin test, the food diary and the leukopenic index). The evidence would indicate that with the allergic diagnostic and therapeutic methods now available, properly employed, treatment should be successful in at least 70 per cent of migraine cases.

Diet in Promoting Nitrogen Gain in Nephrosis—In two patients with the nephrotic type of chronic interstitial nephritis, one aged 13 years and the other 35, Shih-Hao Liu and Hsien-I Chu studied the nitrogen balances and plasma proteins in relation to diets. With a moderate protein intake, nitrogen retention could be progressively increased by the addition of calories in the form of carbohydrate and fat. The first patient showed a maximal nitrogen gain at 88 calories per kilogram of body weight and the second patient retained the greatest amount of nitrogen at 62 calories per kilogram of body weight. Further increase in caloric intake resulted in no increases in the nitrogen retained. When these patients were fed the optimal number of calories, raising the protein intake increased the nitrogen retention somewhat. The maximal nitrogen retention was reached when 75 Gm of protein was fed in case 1 and 100 Gm in case 2. These amounts corresponded to 2.5 and 1.8 Gm. per kilogram of body weight and constituted from 12 to 13 per cent of the total calories. Feeding more protein did not increase the positive nitrogen balance. The first patient showed a slightly increasing nitrogen retention as higher percentages of animal protein were fed, while in the second patient the nature of protein made no distinct difference. While it is impractical to feed a purely animal protein diet, a diet with at least 50 per cent of its protein of animal origin would seem to ensure the best nitrogen gain. Changes in plasma proteins were slow, even in the presence of marked nitrogen retention. The proteins remained at about the same level in the first case. In the second case they slowly increased during the early part of the study. In the second patient, in whom albuminuria decreased as the study progressed, there was no significant change in the albuminuria in relation to the level of protein intake.

Infections of the Upper Respiratory Tract and Rheumatic Fever—Wilson and her associates observed a large group of rheumatic children. Their observations do not support the conception of a specific etiologic relation between respiratory infections and rheumatic fever. The possibility that the rheumatic child is constitutionally vulnerable to both infections is indicated by the frequency of a simultaneous onset of rheumatic activity and respiratory infection (following a common exciting factor). The greater susceptibility of the rheumatic child to respiratory infection compared with that of a nonrheumatic brother or sister is suggested. Their observations tend to minimize the diagnostic significance of hemolytic streptococci in the pharyngeal flora. The specificity of streptococcal respiratory infections based solely on bacteriologic criteria does not appear convincing in view of the observed comparable carrier rate of hemolytic streptococci in the pharyngeal flora of sick and well children. Immunologic studies show a rise in the titer of antistreptolysin following respiratory infections unassociated with hemolytic streptococci in the pharyngeal flora.

The etiology of the rheumatic sequels following scarlet fever is still controversial. During the authors' observations the occurrence of scarlet fever during severe carditis did not appear to influence the course of the latter. Respiratory infections in a rheumatic child seem to bear no more specific etiologic relationship to rheumatic disease than would be attributed to similar episodes occurring in the tuberculous child.

Diabetes Mellitus with Pernicious Anemia—Jolliffe and his co-workers studied two subjects having combined pernicious anemia and diabetes over a hospital period of six and nine months, respectively. One patient entered in a state of severe diabetic ketosis and in a relapse of the anemia, and the other in a relapse of the anemia with many psychotic manifestations. Diabetes developed following treatment for the anemia by parenteral injection of liver extract, iron by mouth, and high caloric and high protein diet over a period of three months. The carbohydrate tolerance of both patients was studied on low and high protein diets, with the following conclusions: 1. High protein diets in the two cases markedly reduced the carbohydrate tolerance. This reduction in tolerance cannot be explained by an increase in calories or by the extra carbohydrate made available from the excess protein. 2. A simultaneous high carbohydrate diet apparently prevented the immediate deleterious effects of the excess protein from becoming apparent. Ultimate results were qualitatively similar to those observed in previous studies when low carbohydrate diets were employed. 3. The loss of carbohydrate tolerance as a result of the high protein diet is not temporary. The tolerance remained impaired in one subject for at least twenty-five days, and in the other for at least six months. 4. Insulin, when given in amounts sufficient to prevent either long continued or severe glycosuria, does not ward off the deleterious effect of excess protein in the diet.

Intestinal Stasis in Low Mineral Diets—Robertson and Doyle believe that the mineral poor diet used in their experiments on rats had in all probability a much lower mineral content than even the poorest human dietaries, but it is possible that the long continued consumption of a diet partially deficient in these factors may also lead to intestinal stasis. Constipation is a prevalent malady among civilized peoples. Many of the highly processed foodstuffs which are much favored, such as white flour and sugar are very low in minerals. Approximately 50 per cent of the total calories in an average diet are derived from these two sources, and in the diet of the poor the percentage is often higher. The common method of boiling vegetables in which the cooking water is discarded no doubt leads to great losses of the mineral salts, such as potassium. Overindulgence in table salt also increases the potassium loss. The combination of all these factors may perhaps play a part in the production of constipation. It appears that both potassium and calcium salts must be added simultaneously to the deficient diet to prevent the stasis that would otherwise occur. Numerous investigators working on other physiologic problems have emphasized the importance of the potassium-calcium balance in maintaining the well being of animals. It is possible that

the high potassium content of some laxatives is a factor in their laxative effect, especially as the calcium intake is high. Human milk is more laxative than cow's milk. This may possibly be due to its higher potassium-calcium ratio.

Antirachitic Potency of Cod Liver Oil and Viosterol—Russell and his associates found that the response of the white rat to antirachitically equivalent amounts of cod liver oil and viosterol, determined curatively, is the same when the two sources of the factor are fed on a preventive basis. This result is strikingly different from that obtained in the chicken, in which species the viosterol form of the antirachitic factor is much less effective than the cod liver oil form when compared on a preventive basis. The minimum protective dose on a preventive basis is between 2 and 10 curative units per fifty grams of ration. The unit or 1+ level, determined curatively, affords only partial protection when fed on a preventive basis.

Placental Extract in Prevention of Measles—McKhann and his associates observed that placental extract can be prepared in large amounts and can be made available for the large scale prevention or modification of measles. Attempts to refine and concentrate the measles antibody have resulted in preparations of less potency than the extracts containing all the globulins. However, the refined preparations can be passed through Berkefeld filters and may therefore be deemed safer to use. The results in a series of 1,258 cases demonstrate that the refined extracts, although less active than the crude preparations, are still effective in the prevention or modification of measles. However, this number of tests is inadequate to permit the determination of the best fraction of the extract to use and the dosage required in children of various ages and at various stages of the incubation period of the disease. The scarlet fever and diphtheria antibodies in placental extract appear to be almost entirely in the pseudoglobulin fraction, whereas the measles and poliomyelitis antibodies appear to be distributed throughout several protein fractions. The tissue protein insoluble in acidified salt solution contains no diphtheria antitoxin but does contain the antibody neutralizing poliomyelitis virus. It has not been tested for activity against measles. Reactions following the injection of placental extract, although infrequent appear to be due in some measure to the inclusion in the finished extract of variable amounts of a specific tissue protein. A method of preparation and administration of extract to eliminate reactions is at present under investigation.

Masked Mastoiditis—Bloch and Merolla present the cases of 119 infants suffering from gastro-enteritis and otitis media as evidence in favor of the clinical entity of masked mastoiditis. These patients were admitted from the free dispensary the clientele of which is composed largely of underweight, undernourished infants. Their ages varied from a few weeks to 13 months. The clinical course of the disease revealed three

stages. In stage 1 the nutritional progress of the infant was suddenly halted by fever. Examination revealed otitis media. Following myringotomy or spontaneous perforation of the ear drum, fever subsided and the few ounces lost were frequently regained. The ear drainage persisted. Stage 2 was characterized by occasional vomiting, an increase in the number of stools, which became slightly watery, a gradual loss of weight and a low grade fever. Stage 3 set in from several days to two or three weeks following the opening of the eardrum. The temperature rose from 3 to 5 degrees, and simultaneously the weight fell from 8 to 30 ounces. The infant then presented the common picture of acute intestinal intoxication. Diarrhea and vomiting became severe, dehydration was rapid, weight fell in spite of supportive therapy, anorexia was common, the infant was apathetic and rarely cried. Unoperated or late operated cases usually proceeded to athrepsia, cachexia and death. In some instances stage 1 was rapidly followed by stage 3. In another small group a milder course was observed, in which dietetic measures proved unavailing, whereas mastoid antrotomy resulted in rapid recovery. It is the authors' opinion that the mastoid infection set in coincident with stage 2, but the failure of the infants' resistance precipitated the profound toxemia of stage 3. The diagnosis of masked mastoiditis depended entirely on the clinical picture described. The classic symptoms and signs of mastoiditis were rarely present. The roentgen examination was not relied on, since many proved mastoid infections produced normal roentgenograms. The swelling of the posterior superior canal described by Lyman frequently occurred too late to be of value.

Encephalitis in Case of Trichinosis—Gordon and his co-workers cite a fatal case of trichinosis in a girl, aged 14 years, who presented a predominating picture of encephalitis throughout the entire course. The three generally accepted diagnostic criteria of the disease were absent: gastro-intestinal symptoms, muscular tenderness and eosinophilia (until the day preceding death). Myocarditis, cerebral congestion, and edema and toxic encephalosis were found at necropsy. Studies of the diaphragm, psoas and rectus abdominis disclosed heavy infestation by the parasites in the early stages. The changes in the brain were scant in proportion to the pronounced clinical picture of encephalitis. Blood studies of five members of the same family affected at the same time are presented. Trichinosis of the right deltoid was found in a brother, who presented a transitory encephalitic picture and recovered.

Ringworm Due to Allergic Unbalance—Browning suggests that ringworm of the extremities is a complication of hypersensitiveness rather than that hypersensitiveness is a complication of ringworm disease. When the patient is placed in a state of "allergic balance," the primary lesion heals quickly without any treatment directed toward the trichophyton. Patients are examined as for other allergic conditions, especially allergic conditions of the skin. Microscopic examination is positive for a fungus in most cases. Most mild cases respond to the ordinary methods of treatment because it is probable that these methods restore an "allergic balance" to the affected parts. Thirty cases are presented, most of which were of a severe type, but the results obtained were excellent. Other allergic manifestations were present in a large proportion of the cases. All the patients were hypersensitive to many allergens. The patch test is usually negative unless there is a superimposed contact dermatitis. The use of trichophyton is unsatisfactory for diagnostic purposes. Improvement usually begins within two weeks if the case has been correctly diagnosed and if instructions have been followed.

Nutrition of Premature Infants Given Antirachitic and Antiscorbutic Food—Horeish and Russell give the results they obtained in the feeding of fifty-three premature infants. Of these eleven died and the remainder received at the hospital for an average of six months the same milk food, twenty-two from birth and twenty from the age of from 2 to 5 weeks. The milk food used was a powdered acid protein milk similar to casein and lactic acid milks and had a pH of 4.6. Its acidity was obtained by adding 20 cc of lemon juice to milk in which lactic acid has been produced by controlled bacterial fermentation. The lemon juice provided the antiscorbutic factor which has been found adequate for the cure of scurvy in infants. The fat of the milk is a mixture of animal and vegetable fats including biologically tested cod liver oil and has character numbers that are practically identical with those of human milk. The cod liver oil content of the milk is 3.8 cc per quart. Carbohydrate, in the form of corn syrup was added as deemed necessary to meet the carbohydrate and caloric requirements of the individual infants. Orange juice was administered in the second week starting with a dose of 1 cc daily and reaching a maximal dose of 15 cc daily in the sixth week. Saccharated

ferrous carbonate in a dose of 0.5 Gm three times daily was started by the second week. The infants showed an excellent gain in weight and approximated closely the ideal weight as portrayed in Wetzel's standard curve. The average daily gain in weight was equal to and in many instances surpassed the average daily rate of gain of premature infants in the series of other observers. Excellent muscle development and tissue turgor was found in all cases. The incidence of gastro-intestinal disturbances of the so-called nutritional type was low and their duration was brief, the infants being free from purely nutritional disturbances during 98.6 per cent of the period of observation. While the incidence of respiratory infections was relatively high, their severity as judged by their duration was mild, the entire group of infants being actually free from respiratory infections 94 per cent of the time. Rickets was prevented in each instance as judged by weekly roentgenograms of the wrist and by monthly determinations of the blood serum calcium and inorganic phosphate. The physiologic anemia of premature infants was not prevented by the liberal administration of saccharated ferrous carbonate. The authors believe that the distinct qualities that make the milk a particularly valuable food for the rearing of premature infants are its high protein, high mineral, high vitamin and reduced fat content.

Use of Irradiated Blood in Cancer—Hyde has accepted the present view that surgery, x-rays and radium are the only methods in use today that are of proved value in the attack on cancer. He uses x-rays in the form of a secondary irradiation. By the use of autogenous blood the cancer patient does not show a reaction and the normal or noncancer patient does. The use of these injections of blood in malignant disease produces benefit which warrants its use, but not by the untrained person. A spectroscopic difference has been demonstrated between the irradiated "cancer" blood and normal blood. The precipitate lowers the hemoglobin in the cancer blood and not in the normal blood. Not one patient in the author's 4,000 blood injections has shown a bad result. Internal and external cancers can be treated in the same way by intravenous injections. Dressings of irradiated blood have been applied to external cancer, and about the same amount of benefit has been noticed as was produced by intravenous injections. The skin does not have to be protected, as this blood appears to affect the cancer only. The fact that the blood reaction factor before cancer is demonstrable makes the method of value at that stage, since the use of this method of treatment may be prophylactic. No better results are obtained by using larger amounts of blood, about 7 cc is enough. The author uses 20 cc, because it is a convenient amount to work with.

Early Diagnosis of Gastro-Intestinal Cancer—Jelks states that emaciation, tumor, obstruction with persistent vomiting and severe hemorrhage, occurring in a person of the cancer age unquestionably indicate the presence of a malignant growth, but that, if the patient manifests such marked symptoms as these before treatment is instituted, his chance of recovery is slight and that, if progress toward cure is to be made, other and earlier occurrences in the patient's health life must be recognized. He lists seven of these which appear relatively early. 1 Although alternating constipation and diarrhea are apparently contradictory evidences, yet a period of constipation, followed by one of diarrhea, is very frequently a sign of cancer of the large intestine. The constipation is often thought to be characteristically progressive, but it is, in fact, when observed by the patient, usually intermittent until the final closing off of the alimentary canal is complete. 2 Vomiting sometimes occurs early in the progress of the growth. It likewise may, and usually does, come 'in spells' a long time before complete obstruction develops. 3 Pain in the epigastrium or lower part of the abdomen, which the patient usually calls "indigestion" and which may or may not be related to the taking of food, should suggest the likelihood of a serious lesion in the digestive tract. 4 The patient often complains of a sense of fullness after eating and of distention following meals, or even at other times in the twenty-four hours. The discomfort from this distention may be referred to the epigastrium or to the lower half of the abdomen. 5 Sometimes one of the first evidences of the disease is loss of appetite. Anorexia is in no sense diagnostic, but it frequently suggests the correct solution of the patient's problem. 6 The presence of anemia, which may be recognized by the doctor or by the patient because of pale-

ness or dizziness, is not an infrequent early sign of cancer, especially of the right intestine. 7 Occasionally a patient complains merely of weakness, which may be a very early sign of cancer and may result either from occult bleeding or from a general disturbance of the digestion.

Typhus-like Fever Contracted from Opossum Fleas.—The Chapmans identified five cases of what they consider to be typhus fever of the endemic variety. In two cases, the only history of exposure was through fleas infesting opossums. That neither patient had typhus but some similar disease and that the patients had typhus but received the infection through some agent other than those at present recognized by students of the disease are possibilities which are disposed of, as the disease could have been only typhus or some other closely allied disease. Rocky Mountain spotted fever was eliminated from consideration by the type of eruption and absence of severe nervous and mental symptoms, and the exposure to the fleas of the opossums was the only probable source of inoculation. Opossums sometimes invade rat nests and may perhaps eat dead rats, since they devour other carrion. It would then be possible for the opossums to have become infested from dead rats or from rat nests. Also in substantiation of this possibility is the fact that fleas carry the virus as long as fifty-two days after the infective feeding, and further that the virus even multiplies within the fleas, so that it is not necessary to postulate a recent contact between the rats and rat nests and the opossums. The possibility is that opossums actually have typhus, as do rats, and that the virus was transmitted through the opossums' own ectoparasites rather than through adventitious fleas. Dyer's recent work has shown that woodchucks, house mice, meadow mice and white-footed mice all may have typhus, and it does not seem at all improbable that the opossum may also acquire the disease. Experiments are now under way to determine whether or not this is true.

Early Ocular Sign in Facial Paresis—Cohen states that the following sign is present at an early stage, often before there is any demonstrable asymmetry of facial movement, and is late in disappearing when the nerve is recovering its function, e. g., in Bell's palsy. If a normal individual is told to "look upward but keep the eyes closed," the stronger contraction of the orbicularis palpebrarum, in keeping the eyelids together, masks the contraction of levator palpebrae superioris. If there is any weakness of the orbicularis palpebrarum, it can no longer antagonize the contraction of levator palpebrae superioris and the eye tends to open. This degree of weakness occurs in the early stages of facial paresis and late in the recovery stage. In the more marked degrees of facial paralysis in which the orbicularis palpebrarum is grossly affected, no closure of the eyes is possible and the facial paresis is evident.

- *Conjunctivitis Clinical and Bacteriologic Investigation I C Michaelson—p 185
- Iodism S Alstead—p 196
- Some Pages from the History of the Prevention of Malaria M Watson—p 202

Conjunctivitis—Michaelson investigated the bacteriology of conjunctivitis as it appears in Glasgow. He examined 433 patients with inflammation of the conjunctiva and lid margins. Cultures were made from the conjunctival secretion, and in ninety-seven cases direct examination of the smear was done as well. Sixty-two cases were bacteriologically negative. Some organisms are practically unconditionally infectious—that is, their presence in a culture taken from the conjunctiva indicates the cause of the inflammation. Gonococci, Koch-Weeks bacilli and Morax-Axenfeld bacilli belong to such a category. Some organisms are facultative pathogens. Such are hemolytic Staphylococcus albus, Staphylococcus aureus, streptococcus, pneumococcus, pneumobacillus and Bacillus coli. The presence of these organisms may or may not be the cause of the disease. Determination of this will depend on their continued presence in repeated cultures and on the number of colonies present, and the latter factor will again be affected by the stage of the disease. A third group, consisting of Staphylococcus albus-nonhaemolyticus, Bacillus xerosis and Bacillus subtilis are only rarely pathogenic. They are very often found on the normal conjunctiva. Under favorable circumstances they may become pathogenic. A number of these cases were due to nonbacterial causes or to organisms which were overgrown in the culture medium by the staphylococcus. The bacteriologic results in the 371 patients with positive cultures are tabulated, together with the percentage of cases in which a pure infection was present. The author draws the following conclusions: 1 The great variation that exists between the bacteriology of conjunctivitis in Glasgow and other parts of the globe. 2 The importance of using cultures in the bacteriologic examination of the conjunctiva. 3 The fact that the pneumococcus, when found in the conjunctiva, is nearly always group IV. 4 The rareness of "pure Koch-Weeks infection" among adults. 5 The association between dental disease and conjunctivitis due to Streptococcus and Staphylococcus albus-haemolyticus. 6 The frequency of Morax bacillus infection in childhood. 7 The frequency with which the non-hemolytic staphylococcus is associated with corneal complications. 8 The serious chronicity of disorders of the lid following an attack of measles.

- *Mutations in the Tubercle Bacillus Under the Influence of a Tuberculin Sulphoguaiacolic Medium A Sartory R Sartory and J Meyer—p 303

Mutations in Tubercle Bacillus—On the basis of laboratory studies with the tubercle bacillus the Sartorys and Meyer make the following conclusions: 1 The prolonged action of the complex substance present in a precipitate obtained by adding sulphoguaiacolic acid to Koch's tuberculin in the presence of antituberculous serum to a medium for culture of tubercle bacillus has the property of penetrating the waxy sheath of the bacillus and acting on its cell elements. 2 There is then a morphologic modification of the bacillus which shows evolutionary forms, confirming the work of Roman and tending to show that the tubercle bacillus is more closely related to the fungi than the bacilli and could be reasonably classified among the actinomycetes. 3 Under the influence of this substance, loss of virulence is manifested in the medium itself before loss of acid-fastness. Of two virulent strains of human tubercle bacillus and two specimens of sputum with virulent tubercle bacilli received from Gordon Tippet, the authors have observed

that the human bacillus was less resistant to the prolonged action of the experimental medium than the bovine Vallee bacillus. The cultures of the third generation show forms very different from those of the normal tubercle bacillus. The bacilli are slender, very long, or in groups, resembling the characteristic form of the "grasbacillus." Most of them have already lost their acido-alcoholic property. They stain clearly and easily in blue by the Ziehl-Neelsen method and take on the form of branching filaments, endowed with a pronounced power of longitudinal growth. They are apt to divide transversely. The chromophilic and morphologic changes appear even in cultures twelve or fifteen days old. The tubercle bacillus, which they were able to isolate in a specimen sputum, was still less resistant to the influence of their cultural medium. The bacilli were already altered in a second generation and passed from the classic bacillary stage to a filamentous branching form with altered granules. The authors are unable to explain the different actions of the various tuberculous strains.

I. Smith and F. J. Wright—p. 930.

So-Called Acidosis.—Paterson, in discussing the clinical meaning of acidosis or ketosis, states that the metabolism of the fats is profoundly influenced by the balance between fats and carbohydrates and that, if the carbohydrate in the form of starches and sugars is insufficient, the fat will be only partially broken down and acetone and diacetic acid will be formed. This may be brought about because the amount of carbohydrate absorbed is insufficient, or because too much fat is being given. The usual sequence of events, however, is that the carbohydrate present in the food and stored in the muscles and liver is suddenly called on and used up during an infection. The body, deprived of carbohydrate, looks to its store of fat for energy, and ketone bodies are formed as a result. In the majority of children acidosis or ketosis by itself leads to little or no change in the clinical picture. The symptoms attributed to "acidosis" are produced by the factor that produces the acetone—and this is usually an infection. The author concludes that the diagnosis of acidosis is a bad one and should never be used. Rather the process underlying this clinical picture should be thought of. This will rarely be found to be primarily dietetic, but rather infective in origin. A search for the source of the infection, usually nasopharyngeal, should be made, and this should be treated.

Experimental Hyperplasia of the Prostate.—In their experimental production of hyperplasia of the prostate Parkes and Zuckerman gave daily (from six to twenty-eight days) injections of an oil solution of estrogenic material to ten immature male rhesus monkeys, varying in weight from 17 to 48 Kg., and to one immature Guinea baboon. The total amount injected varied between 14 and 30 mg. Six normal rhesus monkeys and one Guinea baboon of equivalent weights were used as controls. The injected animals showed pronounced prostatic changes comprising (1) diminution in the number of true prostatic glands, with a corresponding increase in the amount of fibromuscular stroma, and (2) epithelial growth in the uterus masculinus. The latter change is very conspicuous, and the utricle acquires a large distended lumen lined by as many as twenty-five layers of stratified epithelium. The apparent reduction in the number of true prostatic glands, which are derived from the urogenital sinus, and the corresponding increase in the amount of prostatic fibromuscular tissue may be regarded as part of the general effect of estrogenic substance on the smooth muscle of the accessory reproductive organs. There is good evidence that the effects of the substance are suppressed by the simultaneous administration of progestin, the hormone of the corpus luteum.

Treatment for Anterior Poliomyelitis and Encephalitis.—The experiment of Royle shows that, following the high division of the cord in poliomyelitis, the activity of that organ can be maintained by the administration of ephedrine. He has observed in actual experiments that ephedrine constricts the capillaries. This is followed immediately by a dilatation of the arterioles and venules, so that there is an increase in blood supply. In large doses ephedrine so constricts the capillaries that it leads to a temporary cessation of blood flow in spite of the concomitant dilatation of the arterioles. The consequent anoxemia excites the cord to hyperactivity, as shown by the increase in plastic or postural tone. Small doses of ephedrine (0.0075 Gm.) increase the blood supply by what the author describes as the arteriolar capillary reaction when the capillaries are constricted, the arterioles and venules dilate and, when the capillaries are dilated, the arterioles and venules are constricted. Ephedrine, in addition to keeping up the activity of the spinal cord, also controls wasting and, if given frequently enough, should be effective in the wasting following the edema of the cord in poliomyelitis. It would be easier to prevent the onset of paralysis than to deal with it when present, because the paralysis represents the result of damage to the anterior horn cells from edema. If this edema is long continued, the effects on the anterior horn cells may be permanent. Ephedrine should be given in the postparalytic stage to keep up the nutrition of the muscles until recovery has taken place. Four illustrative cases are presented.

- *Meningeal Spirochetosis and Meningotyphoid J Troisier M Bariéty, Mlle B Erber G Brouet and Mlle J Sifferlen—p 713
Functional Examination of Respiration Du Pasquier—p 716

Meningeal Spirochetosis and Meningotyphoid—Troisier and his collaborators report a case in which a man, aged 31, contracted an acute infection characterized by meningitis and marked conjunctival infection but without important intestinal symptoms. Lumbar puncture revealed pleocytosis, mixed cellular reaction and hyperalbuminosis. The patient suffered a relapse of his meningitis but eventually recovered. Serologic tests of the patient's blood showed a persistent negative reaction to the paratyphoid organisms and a persistently positive reaction to Bacterium typhosum. The complete absence of the usual symptoms of typhoid and the previous numerous (eight) vaccinations of the patient against typhoid raised questions as to the diagnosis. They isolated from the patient's urine between the fourteenth and seventeenth days a spirochete capable of producing a fatal icterus in the guinea-pig. Furthermore, they found that the blood serum of the patient possessed agglutinins and immunins to Spirochaeta icterohaemorrhagica in high dilutions. They conclude that the meningitis was in reality spirochetal and that the typhoid bacillus infection was simultaneous but asymptomatic, owing to the previous antityphoid inoculations.

Chronic Intestinal Amebiasis Prolonged Negativity of Laboratory Tests Case F Pullé and G Acanfora—p 1035
Immunization by Ultraprotones in Cancer G Carosini—p 1039

Bassini's Modified Operation for Inguinal Hernia—Baggio's technic, a modification of Bassini's operation for the cure of inguinal hernia, consists in freeing and excising the hernial sac and the hernial preperitoneal tissues through an incision made in the transversalis fascia, closure of the peritoneum with a lineal suture, reconstruction of the transversalis fascia in a layer by itself and construction of a new posterior wall of the inguinal canal. In the construction of the posterior wall the author uses the abdominal rectus muscle, deprived of its sheath and sutured to Poupart's ligament by means of U sutures in a deep plane, and, fastened to this layer, the inferior edge of the small oblique and transverse muscles, joined with the upper half of the cremaster, in a more superficial plane, and the lower half of the cremaster in the superficial plane. Over this pad the spermatic cord is placed and then covered by the aponeurosis.

Studies on the Etiology of Influenza—Elkeles says that two investigations are important in connection with the etiology of influenza: those of Shope and Shope-Lewis and those of Smith and his collaborators. Shope and his collaborators proved that hog influenza, which is similar to influenza in man, develops by the combined action of a filtrable virus and of influenza bacilli. Smith and his co-workers succeeded in transmitting human influenza to ferrets by means of intranasal inoculation of a filtrable virus obtained from the washings of the throats of patients with influenza. The pathologic picture in the animal is characterized by the presence of fever, purulent rhinitis, general malaise, anorexia, loss of weight, a cough and other disturbances. The intranasal inoculation of hog influenza virus produces the same pathologic picture in ferrets. The author's experiments were carried out with the aim of ascertaining whether human influenza is transmissible to hogs. He found

that the intranasal inoculation of the virus, as well as of cultures of the same virus previously inoculated in ferrets, produces in suckling pigs the same pathologic picture of experimental influenza as that reported by Smith and his co-workers in ferrets. The course of the disease in suckling pigs is more serious when the intranasal inoculation is made with a combination of virus and influenza bacilli. Bronchopneumonic foci are present in severe cases. The emulsion of tissues from bronchopneumonic lesions of suckling pigs when reinoculated in ferrets, produces the same characteristic clinical and pathologic picture of experimental influenza. The inoculation of influenza bacilli alone, without virus, produces neither pathologic signs nor anatomic changes. The author states that a close relationship exists between the virus of human influenza and that of hog influenza and emphasizes the relation of the virus and the bacilli of influenza in the development of the disease. He advises the use of suckling pigs in further research work on influenza. Suckling pigs are more suitable than ferrets for research work and react to the inoculation more easily than the latter, with the development of bronchopneumonic lesions, which may be of a graver type if they are inoculated with the virus-bacillus combination.

Giant Vesicular Ampullous Emphysema Simulating Total Pneumothorax Case I R Steinberg and D Vivoli—p 1292

Tuberculous Etiology of Erythema Nodosum—Cibils Aguirre says that, in five out of eight cases of erythema nodosum, tubercle bacilli were identified by direct culture of material from the erythematous nodule in one, by intraganglionic inoculation in guinea-pigs in one, by successive reinoculations and cultures in all five and by histologic examination of sections of the nodules in one. In one of the three cases in which negative results were obtained the inoculation was made with material obtained by biopsy from the erythematous nodule fifteen days after the appearance of the nodule, in another case, the material used in the second inoculation was taken from a guinea-pig inoculated six months previously, in the third case, the experiments were stopped because of infection of the animals. The author says that the results of his work, by which the presence of tubercle bacilli in the erythematous nodules was verified, constitute the most complete bacteriologic proof of the tuberculous etiology of erythema nodosum.

Experimental Calculosis in A Avitaminosis—Escudero and Bosq detected calcareous concretions in the renal tissues of five rats out of a group of six in which experimental A avitaminosis had been produced. The position of the calculi in the renal tissues as well as the aggregations of cells at certain points of the tissues seems to support the opinion that cellular aggregations play a role in the formation of renal calculi. The author believes that an intense congestion of the parenchyma, such as that observed in the renal parenchyma of the animal in which calculi were not as yet formed, is probably a disturbance as constant as xerophthalmia in A avitaminosis. He concludes that the formation of renal calculi should be considered one of the disturbances caused by A avitaminosis.

- *Vaccination Resistance of the New-Born J von Lukács and D von Moritz—p 1
*Latent Serum Reaction E Barla Szabó—p 5
Tissue Reactions in Serum Disease E Barla Szabó—p 8

Vaccination Resistance of the New-Born—Von Lukács and von Moritz investigated why there are less positive vaccination reactions in the new-born than in older nurslings by comparing the reactions of newly born infants, vaccinated on the second day after birth, with the reactions of older nurslings. They found that newly born infants have a relative resistance to vaccination in that their reaction develops more slowly than that of the older nurslings. The papule becomes

relatively larger in the new-born, but the surrounding area is small. There is hardly any general reaction (fever) and the increase in weight is not impaired. The authors think that this deviation from the usual vaccination reaction is the result of a deficient antibody formation in the new-born.

Latent Serum Reaction—Barla-Szabó employed Kaufmann's cantharidal test to demonstrate the latent serum reaction in twenty children, aged between 3 and 12 years, in whom the administration of normal horse serum caused no clinical manifestations. In some of the cases not even Kaufmann's tissue reaction disclosed changes. In other cases Kaufmann's test disclosed the reactivity of the organism to be altered in the same manner as in those cases in which the serum reaction causes clinical manifestations.

*Serodiagnosis of Tuberculosis by Means of Flocculation Reactions. E. Dissmann and Maria Dissmann-Wosak—p 176

*Therapy with Ultrashort Electric Waves Particularly in Tuberculous Disturbances O. Schedtler—p 189

Selective Upper Thoracoplasty in Pulmonary Tuberculosis N. W. Antelawa—p 200

Serodiagnosis of Tuberculosis—Dissmann and Dissmann-Wosak point out that the improvement of the flocculation reactions for syphilis and the observation that they are a manifestation of a reaction of antigen and antibody and thus a generally applicable immunity reaction led to the demonstration of the antibodies in the serum of tuberculous patients. Thus far it was generally the indirect method of the deviation of the complement that was employed. However, the especially purified and fractionated extracts of tubercle bacilli, which proved to be effective antigens in the complement fixation test, seemed to promise specific reactions in the flocculation system. The authors made various flocculation reactions on about 1,200 blood specimens from 480 patients with pulmonary tuberculosis, from thirty-six with other disorders and from 103 healthy persons. They employed (1) the Meimcke clarification reaction (II) with the especially prepared extracts as microreaction, as curvature reaction (accumulation of sediment in the bottom curvature of the test tube) and as centrifugation method, (2) the latter centrifugation method with the addition of the antigen according to Witebsky-Kuhn-Klingenstein, and (3) the complement fixation reaction according to Witebsky-Kuhn-Klingenstein. A comparison of the microreaction, the curvature reaction and the centrifugation method indicated that the curvature reaction in its second modification is the best method. It is advisable to perform the microreaction and the curvature reaction together. The strongest Meimcke antigen occasionally produces nonspecific reactions. The Witebsky-Kuhn-Klingenstein antigen with the standard clarification extract is of great value in the centrifugation method. Negative reactions have been observed in open, more or less extended forms of tuberculosis. Considerable changes in the disease process are accompanied by fluctuations in the intensity of the reactions. The authors think it probable that the occurrence of positive reactions in healthy persons may be the result of pulmonary infiltrates of short duration. They call attention to the differential diagnostic significance of seroreactions.

Ultra-Short Wave Therapy in Tuberculosis—In preliminary experiments with ultrashort waves Schedtler gained the impression that the heat effect seems to be the chief factor in ultra-short wave therapy. He therefore resorted to it in tuberculous processes in which heat, hyperemization and anti-inflammatory measures were indicated. He treated fourteen patients in whom pulmonary tuberculosis was complicated by dry pleurisy, with ultrashort waves of from 35 to 6 meters and obtained favorable results. Six cases of wet pleurisy, most of them of tuberculous etiology, were likewise treated with ultrashort waves. This treatment never produced prompt cessation of the exudation, but four refractory cases were led to resorption and adhesion, while in the two other cases the treatment remained ineffective. Three cases of tuberculous pleural empyema were not influenced by the

treatment, while two patients who had nontuberculous pleural suppurations recovered. In fistulating glandular processes and in tuberculosis of the joints and bones, ultra-short wave therapy was given in addition to open air rest cure and to cod liver oil treatment. None of these cases showed a noticeable improvement as the result of the ultra-short wave therapy, which, however, proved highly effective in three cases of nonspecific chronic multiple arthritis. In four cases of tuberculous peritonitis, the ultrashort waves produced considerable improvement. The symptoms of intestinal tuberculosis likewise were favorably influenced. In view of the fact that patients with pulmonary tuberculosis are highly sensitive to all types of rays, the author was cautious in the application of ultrashort waves to these patients, and his observations justified this attitude. Convincing therapeutic effects were not produced. Summarizing, the author points out that ultra-short wave therapy seems to be justified within certain limitations. He was unable to demonstrate specific actions and thinks that this new form of ray therapy can be employed whenever intensive heating is desirable. This applies particularly to the various forms of pleurisy. The analgesic action of the ultrashort rays should be given further attention. In the author's observations on the effect of ultrashort waves in tuberculous processes of the larynx and of the eyes, thus far, he gained the impression that they promote the healing process, provided the general condition is good and the treatment is continued for a sufficient length of time.

*Occurrence of Local Edema in Human Subjects C. Ernst—p 745

Borderline Condition of Epidemic Encephalitis E. H. Romberg—p 747

*Rhizomelic Spondylosis H. Engel—p 752

Local Edema—On the basis of numerous experiments, Ernst reaches the conclusion that patients with vasoneurosis and hypertension have a tendency to local edema. He thinks the fact that the facial expression of such persons often changes rapidly from an enervated, prostrated expression to a condition of high turgor indicates the same. The site and intensity of the local edema is largely independent of hydrostatic conditions, but meteorologic and temperature changes as well as psychic changes in the patient exert an influence on the local edema. Thus the vasoneurotic diathesis is characterized not only by vascular anomalies but also by changes in the tissues. The author thinks that vasoneurosis has a causal connection with and creates a predisposition for a number of disorders, such as gastric ulcer, red hypertension, Raynaud's gangrene, ulcerous colitis, certain forms of asthma and some forms of cystitis. Moreover, vasoneurosis often concurs with certain types of glaucoma and with Ménière's syndrome.

Rhizomelic Spondylosis—Engel reports a case of rhizomelic spondylosis in a man, aged 32. He considers the case worthy of attention because, after the man had been completely immobilized for nine years, the spinal column as well as the hip joints being ankylosed, he underwent an operation to enable him to sit up. Pseudo-arthroses were produced in the trochanter regions of both lower extremities with the result that the patient is able to sit up and use his arms and hands, for only one of the shoulder joints is slightly impaired in its motility.

Revival After Exsanguination—Winkelbauer removed a definite amount of blood from the femoral artery of a dog into a Percy tube, after which the blood was allowed to escape until the disappearance of the pulse and heart tones and the arrest of breathing. After a variable waiting period the blood was reinfused either into the jugular vein or into the carotid artery in the direction of the heart or of the brain or, by means of a glass canula, in both directions. The experiments were con-

trolled by graphic recording of the pulse, auscultatory control of the heart tones and the use of electrocardiograms. The mode of death from exsanguination was not always identical. It was caused by arrest of the heart, the respiration or the vasomotor center. The author took advantage of the pre-terminal pause, which could always be observed in the respirations or in the electrocardiogram, to estimate the waiting period before the beginning of reinfusion. This period varied from one half to twenty and one half minutes. The infusion into the arterial system proved to be more effective during this critical period than the infusion into the venous system. The clinical signs of death did not coincide with the suspension of the cardiac activity. Revival was still possible as long as the electrocardiogram showed traces of regulated cardiac action. When the electrocardiogram no longer recorded any traces of cardiac activity, revival was not possible. Out of forty experiments performed by the author on thirty-seven dogs, fifteen were successful in reviving the animal. A complete return to normal in the surviving animals took place after a few hours or days. The electrocardiogram indicated an impairment of the intraventricular conductivity. At times the electrocardiograms resembled those of coronary occlusion with signs of high grade fibrillation. The frequently observed heartblock was regarded as being due to asphyxia.

*Influence of Muscular Activity on Blood Sugar and Blood Catalase H. Koeppel—p. 667

*Carotene and Vitamin A Contents of Human Serum E. Schneider and E. Widmann—p. 670
Cevitamic Acid and Blood Catalase G. Torök, M. Hedry and L. Neufeld—p. 673

*Curves of Serum Color Reaction in Pernicious and Simple Achylic Anemias E. Schmehle and H. Schmid—p. 675

Influence of Muscular Activity on Blood Sugar.—Koeppel points out that catalase, as an oxidation ferment, plays an important part in metabolism. Numerous studies disclosed that the catalase content of the blood is influenced by many factors. The author found that the catalase content of the blood plays a part in the oxidation of the sugar. The relation between blood sugar and catalase was proved by the observation that the two are changed simultaneously, but in the opposite direction, by (1) the administration of carbohydrates, (2) hunger and (3) muscular activity. The dependence of the blood sugar content on the intake of carbohydrates and on hunger was known and has been given therapeutic consideration, but its dependence on muscular activity was not so well understood and consequently has not been given the attention it deserves. It is important in determining the so-called fasting blood sugar value, for, when the blood sugar is tested after the fasting person has had considerable muscular exercise, the value thus obtained is not the same as when the test is made immediately after awakening from a restful sleep. The author thinks that the simultaneous determination of the catalase values may eventually give a clearer insight into the relation between blood sugar and catalase and consequently information about the metabolism.

Carotene and Vitamin A Contents of Human Serum.—Schneider and Widmann show that carotene and vitamin A are present only in the serum, but not in the blood corpuscles. They discuss the methods for the determination of carotene and vitamin A. They observed that with increasing temperature more and more carotene is destroyed and they think that this observation has some significance for the cooking and baking process. They found also that with increasing age the carotene content of the serum increases while the vitamin A content decreases. The vitamin A content, particularly, describes a regular life curve. The authors think that, when a deficiency in vitamin A is studied this life curve should be taken into consideration. The deficiency in vitamin A, which becomes manifest in spite of a sufficient intake, is caused by a functional impairment of the liver. The vitamin A content is important in connection (1) with certain ophthalmic disturbances, (2) with the secondary thyrogenic impairment of the liver and (3) with infections. Little is as yet known about the mechanism of the vitamin A action in the organism. Some

have been of the opinion that it catalyzes the oxidation processes in the liver, while others have maintained that it influences the glycolysis. The latter problem was investigated by several authors and some of them considered the formation of methylglyoxal as the essential factor in glycolysis. The authors likewise studied this problem and found that, if measured on the increase in methylglyoxal, the addition of carotene produces a slight increase in the glycolysis. Vitamin A alone effects no increase, while the combined administration of carotene and vitamin A produces a noticeable increase. Cevitamic acid exerted no influence on the glycolysis.

Color Reaction of the Serum in Pernicious Anemia.—Schmehle and Schmid determined with the step photometer in thirty normal serums the average normal curve of the color reaction of the serum. This average approximately corresponds to the curve most frequent in normal persons. The serum color index is considerably increased in severe cases of pernicious anemia and decreases rapidly under the influence of liver therapy. In patients in whom the color index reaches normal or subnormal values, the tendency to relapse is not so pronounced as in patients in whom the color index remains rather high in spite of normal erythrocyte values, for the high color index shows that there is still increased hemolysis. The authors discuss the color index in simple achylic anemia. They apply this term to a form of secondary anemia, accompanied by achylia or subacidity, which often exists for many years and has a blood picture that somewhat resembles chlorosis. The chief symptom is a disturbance in the gastric secretion caused by atrophy of the mucous membrane of the digestive tract. Thin and brittle nails are another sign of achylic anemia. The color index is low in achylic anemia, which indicates that it is not a hemolytic anemia, but it increases as the hemoglobin increases. The hemoglobin content can be increased by medication with reduced iron. Relapses are quite frequent in this form of anemia, but they never endanger the patient's life.

*Acceleration of Nylander's Sugar Reaction G. Lepehne—p. 649

Nylander's Sugar Reaction.—Lepehne observed that the presence of lead acetate considerably accelerates Nylander's reaction. He found that, in a urine which had been clarified with lead acetate for the purpose of quantitative polarimetric examination, Nylander's test was completed within a short time. Further studies revealed that, if Nylander's reagent was saturated with lead acetate, the black precipitate developed much more rapidly than when ordinary Nylander's solution was used. In trying to find the optimal composition of the new reagent, the author observed that the alkalinity of Nylander's solution is reduced by the addition of lead acetate. In order to prevent a disturbance in the reaction in strongly acid urines because of the reduced alkalinity, he prepared Nylander's solution with a 12 per cent instead of a 10 per cent solution of sodium hydroxide, and he mixed one part of the reagent with one part of the urine. This solution with its increased alkali content is carefully heated, then, while it is heated again, small amounts of finely powdered lead acetate are added until the solution is hypersaturated. The opaque fluid is cleared by filtration. A sediment, which precipitates later, does not disturb the reaction. Overheating must be avoided in order to prevent the formation of lead oxide and the resulting yellow coloration of the solution or of the sediment. The author states that he worked with this modified Nylander reagent for several years and found it reliable. If this new reagent is used, the black sediment, indicative of the presence of sugar, appears after from one-half to one minute of boiling, while the original reagent required from three to four minutes or longer. A slight protein content of the urine or strong urobilin and indican contents do not interfere with the reaction. The author mentions several other investigators who suggested the use of lead acetate for the improvement of Nylander's reaction.

*Aspects of Spinal Cord in 'Cured' Funicular Myelitis L Bouman and M Bielschowsky—p 538

*Late Lesions of Human Brain Caused by Roentgen Rays T Markiewicz—p 548

The Spinal Cord in a Case of "Cured" Funicular Myelitis—Bouman and Bielschowsky report the history of a man who died of carcinoma of the stomach in 1934. In 1920 and 1921 he had had symptoms indicating the existence of pernicious anemia with involvement of the spinal cord. At that time the patient was given arsenic therapy. He recovered and was in good general condition for twelve years, blood changes as well as spinal symptoms being absent. The achlorhydria and the cerebral symptoms, which the patient developed toward the end of his life, were caused by the gastric carcinoma, for changes in the blood indicative of recurrence of the pernicious anemia were not evident. The histopathologic aspects of the spinal cord of this patient are noteworthy. On macroscopic observation, the transverse sections revealed nothing abnormal. Not until stains were applied to the medullary sheaths did changes become evident, which differed from those usually observed in funicular myelitis. A transverse section of the dorsal spinal cord did not disclose the gaps that are typical for funicular myelitis in the posterior, lateral or anterior columns but the section did disclose characteristic spotted markings resulting from the confluence of smaller foci of medullary shadows and absorbing less of the hematoxylin of Weigert's stain. In these medullary shadows the normal number of axis cylinders was hardly reduced. They conclude from the histologic aspects of this spinal cord that the changes of funicular myelitis are largely reversible. They think that the organ preparations that exert a favorable influence on the blood picture of pernicious anemia should be given in much larger doses in cases in which the spinal cord is involved, for it is more difficult to influence funicular myelitis.

Late Roentgen Lesions of the Brain—Markiewicz reports a case in which a man, aged 34, had paresthesias of the scalp, epileptic attacks of the Jackson type, amaurosis and paraplegia of the lower extremities five years after the first roentgen irradiation and one and one-half years after the last one and a roentgen ulcer of the scalp in the occipital region a little later. The time that elapsed between the first and last irradiations and death was four and seven years, respectively. Anatomic studies disclosed multiple symmetrical necroses, some of which were hemorrhagic and most of which were in the cerebral medulla and almost exclusively in the occipital and parietal regions, at the site of the severest cutaneous changes. There also were signs of impairment of the interstitial tissues, and deposits of substances were found that greatly resembled the colloidal degeneration described by Alzheimer or the coagulation necrosis of Spielmeyer. However, in contradistinction to those authors, Markiewicz detected the vascular changes not only in the brain but also in the vessels of the pia. The changes observed in this patient correspond to those which Scholz produced by means of roentgen rays in animals, except that in the patient they were more advanced. There is a resemblance not only in that they are of circulatory origin but also in that the nervous parenchyma proved resistant to the roentgen rays. The changes in the patient supplement the observations made by Scholz in animals that it was possible to determine a reduced reactivity of the ectodermic as well as of the mesodermic interstitial tissues. Then there was a parallel process to the necroses namely, extensive deposits of colloidal substances which Scholz observed only in their beginning stages in and near the vessels. Whether the peculiar colloidal transformation of the vessels is the cause of the circulatory conditioned necroses cannot be definitely determined. At any rate, it appears that the deposits of colloidal masses themselves may later produce necrosis. The long latent stage between the application of the rays and the manifestation of the clinical signs is known from roentgen injuries of other organs, particularly those of the skin.

*Pneumothorax Pleurisy and Simple and Effective Method of Preventing It I Petrin—p 31

Method of Preventing Pneumothorax Pleurisy—Petrin introduced from 2 to 4 cc. of sterile olive oil into the pleural cavity of rabbits and then injected air, in quantities from 80 to 150 cc., at intervals of from seven to ten days. When oil was not introduced, exudates resulted, while, if oil was introduced, the pneumothorax became complete and the pleura showed thickening but there was no exudate. Examination of the thickened pleurae disclosed inflammatory granulation in the course of becoming fibrous, that is, there exists a fibrous pleuritis in which the reparative process (granulation tissue) predominates over the alternative and exudative processes. Encouraged by the effects of oil injections in animals, the injection of oil was employed in 105 patients. At the second and third refilling of the pneumothorax, from 2 to 4 cc of sterile olive oil is introduced into the pleural cavity by introducing the oil through the pneumothorax needle by means of a syringe. The majority of patients complained of severe thoracic pain on the day the oil was introduced and many had a considerable rise in temperature. Roentgenoscopy disclosed that a sinus exudate developed in all patients, and in four it rose to the dome of the diaphragm. However, after about two weeks the exudate had become resorbed. A high exudate that necessitated a puncture or the premature interruption of the pneumothorax did not develop in any of the cases. A pneumothorax should never be made complete at once, but only fifteen days after the introduction of the oil. The author concludes that the clinical and experimental results of the endopleural oil injection justify a wide application of this treatment.

*Kaposi's Disease as Systematized Angiomatosis F J Lang and L Haslhofer—p 68

*Experimental Studies on Problem of Tobacco and Cancer O Schurch and A Winterstein—p 76

Kaposi's Disease as Systematized Angiomatosis—Lang and Haslhofer point out that the opinions about the nature of the disorder designated by Kaposi as sarcoma idiopathum multiplex pigmentosum are still divided. The authors think that the different opinions about the nature of Kaposi's disease are due to the extraordinary manifold microscopic aspects presented by the disease. They observed two cases of Kaposi's disease. They point out that the tissue changes consist in sprouting and dilatation of the capillaries, hemorrhages and proliferation of the connective tissue cells. These changes are accompanied by pigment formation. The disorder involves primarily the corium and, occasionally, the subcutaneous connective tissue, whereas the epidermis is only secondarily involved. The authors describe the histologic aspects and reproduce photomicrographs. The tissue changes of the internal organs that may be involved correspond to those of the skin. In regard to the pathogenesis most investigators seem to agree that the Kaposi 'sarcoma' is due to vascular changes. Authors, who considered the condition tumorous called attention to the microscopic structure and to the apparent metastasization. Other investigators, however, cited factors that contradict the sarcoma nature of Kaposi's disease. The authors themselves reach the conclusion that Kaposi's disease is a systematized hemangiomatosis and consider the later developing spindle-cell nodules transformations and retrogressive forms of vascular tumors which finally end in complete cure. That the disorder is a hemangiomatosis is proved not only by the clinical aspects but also by the fact that angiomatous formations often have a multiplicity of first traces. This latter factor

disproves the metastatic nature of the changes in the internal organs. The spontaneous recovery from the vascular tumors is another factor that contradicts the sarcomatous nature.

Tobacco and Cancer—Schürch and Winterstein analyzed tobacco tar and found that it is free from polycyclic, aromatic hydrocarbons. The cancer-producing hydrocarbons that are found in coal tar are lacking in tobacco tar. The authors tested the cancerogenic action of tobacco tar on the skin and mucous membranes of mice and rabbits. They found that painting with tobacco tar, either alone or in connection with mechanical or thermic irritation, does not produce carcinoma. The various fractions of tobacco tar likewise proved to be free from cancerogenic action. In rabbits the general condition of which had been impaired by a high cholesterol diet and by application of coal tar, it was possible to produce tar warts and carcinoma by means of tobacco tar. The authors conclude that tobacco tar is a factor in the pathogenesis of cancer only in case a predisposition exists.

Alcoholization of Intercostal Nerves in Treatment of Pulmonary Tuberculosis—According to Rabboni, Leotta's method of restricting the respiratory excursion consists in injecting 2 cc. of 95 per cent alcohol into the intercostal nerve. To accomplish the desired effect, Leotta injects four intercostal nerves on both sides. The technic is simple and certain if the needle is introduced into the triangular space Leotta designates as the costopleural triangle. To avoid pain, 0.5 cc of 4 per cent procaine hydrochloride solution is injected before the alcohol is introduced. The treatment results in diminishing the sensitivity of the skin, immobility of the ribs and a diminution of the respiratory excursion accompanied by a lowering of spirometric values and of the vital capacity. The author feels that this condition must be maintained, regardless of the type of tuberculosis, for not less than two years. The return of rib mobility is recognized by a return to normal vital capacity and by fluoroscopic examination. Injection of the nerves is to be repeated as a rule after from three to four months. It is not necessary to combine this with any other method of collapse therapy. The advantages of the method are that the pleura is not harmed, a complete anatomic and functional restitution takes place, and it is free from any danger. The method is indicated whenever pleural adhesions make it impossible to induce a pneumothorax and when bilateral immobilization is desirable. It is particularly successful in cases presenting fibrous induration. The author further advises it for hemoptysis that is difficult to arrest.

Simultaneous Intra Uterine and Extra Uterine Pregnancy A. Katz—p. 1054

Aschheim-Zondek Reaction in Chorionepithelioma—According to Koehler the Aschheim-Zondek reaction is of greater significance in the diagnosis of cystic mole and of chorionepithelioma than in the diagnosis of pregnancy. He concedes that the positive Aschheim-Zondek reaction as such is no help in the recognition of the presence of a degenerated ovum, for its positive outcome indicates only the presence of active chorion tissue. In case of degenerative processes on the ovum, that is in case of cystic mole, the hormone content is considerably

greater, in that each cubic centimeter contains from 250 to 500 mouse units, compared to from 20 to 30 mouse units in normal pregnancy. The assumption of a malignant degeneration, in the absence of other symptoms, is justified if a positive Aschheim-Zondek reaction persists two or three weeks after the discharge of an apparently normal ovum or from sixty to ninety days after the expulsion of a cystic mole. However hemorrhages will generally suggest the malignant degeneration of an ovum, even before this period has elapsed. If, following the expulsion of a normal ovum or of one with cystic degeneration, the Aschheim-Zondek reaction again becomes positive after having been negative, malignant degeneration is likely, particularly if there are hemorrhages. For this reason, the Aschheim-Zondek reaction must be repeated at least every month in every case of cystic mole, so as not to miss the best time for the treatment of chorionepithelioma. The author gives the clinical history of a case of cystic mole, in which the suspicion of a chorionepithelioma was supported by the outcome of the Aschheim-Zondek test and in which it was corroborated by the total extirpation of the uterus, without previous exploratory curettage. However, he reports another case in which the erroneous outcome of the Aschheim-Zondek test was taken as an indication of a radical therapeutic procedure (total extirpation of the uterus in a young woman), which would not have been done had the Aschheim-Zondek test not failed in this case.

*Antivirus Prophylaxis of Grip E. E. Shtaynshtayder and T. S. Yakobson—p. 623

Relation of Allergic State to Predisposition to Scarlet Fever—Gen and Skrotskiy used the Dick test as the criterion for predisposition to scarlet fever and the intradermal injection of 1 per cent watery solution of Witte's peptone as a test of the allergic state of the organism. Observations were carried out on 516 children ranging in age from 3 to 8 years. Two-tenths cubic centimeter of the solution of peptone was injected intradermally into one arm, while simultaneously the Dick test was applied to the other. The authors found that the reactions of the two are quite similar in their manifestations (redness, swelling, pain) and in the time of appearance and disappearance. They ran a parallel course in 70 per cent of the cases. While 53 per cent of the healthy children reacted positively to the injection of peptone, only 4 per cent of those convalescing from scarlet fever reacted positively. Apparently scarlet fever desensitizes the organism to a nonspecific allergen. The same convalescing children reacted to the Dick test in 14 per cent of the tests. The authors conclude that the allergic state in children acts as a predisposing factor to scarlet fever. Their results favor the allergic character of the Dick reaction and the significance of the allergic factor in the pathogenesis of scarlet fever.

Antivirus Prophylaxis of Grip—Shtaynshtayder and Yakobson report mass vaccinations against grip. The method consisted of touching up the throats twice daily for two or three days with a grip antivirus prepared at the Metchnikov Institute and consisting of four parts of Pfeiffer bacillus antivirus, two of pneumococcus antivirus, three of streptococcus antivirus and one of Neisseria catarrhalis antivirus. The first vaccination was carried out during October and November 1933, on some 5,000 workers in several machine plants. A second vaccination experiment was carried out during an epidemic flare up in February 1934. A number of controls were not vaccinated. The morbidity from grip during the first month among those vaccinated was 1.1 per cent and 2.8 per cent among the controls, during the second month 2.1 among those vaccinated and 3.7 among the controls and during the third month, 2.7 and 2.8, respectively. In the second experiment 1,123 workers were submitted to the antivirus treatment, while 1,276 acted as controls. The morbidity percentages were 6.5 in the treated group and 12.5 in the controls. The authors conclude that grip antivirus is an effective

tive prophylactic agent in endemic and epidemic grip. The duration of the immunity is not less than one month. Vaccination reduces the incidence of grip to one half. The course of the illness in the vaccinated is shorter. The antiviral may be administered by the method of local application to the pharynx or nose.

Etiology and Treatment of Respiratory Asthma G. F. Gezelle Meerburg—p. 2348

Hypophyseal Reaction in Tuberculosis—Koster and Heeres describe a syndrome occurring in tuberculosis which they consider due to a hyperfunction of the hypophysis. The clinical picture has much in common with hyperpituitarism and with hyperadrenalinism. It consists in moderate obesity, rapid growth of body weight, hyperthermia, erythremia, hypertension, hyperglycemia and glycosuria, purplish red striae on the abdomen, thighs and upper arms, moderate increase in the cholesterol content of the blood, marked increase in the basal metabolic rate, genital anomalies, falling out of hair, moon face and slight kyphosis. The subjective symptoms resulting from the tuberculous changes are pains in the back, shooting pains in the arms and legs, constant fatigue at the slightest effort, headache and vertigo. The author treated six patients, three of whom developed the symptoms after previous treatment for tuberculosis, while the others showed such symptoms in the course of an acute pleural process. No conclusions regarding prognosis were reached.

*Uremia as Cause of Death in Massive Hemorrhage from Peptic Ulcer T. Christiansen—p. 333

Potassium Content of Blood Serum During Fever—Kallós-Defner calls attention to a paper in which Cloetta demonstrated the unreliability of the methods recommended for the demonstration of the potassium content of the blood serum and in which a new method was described. Since Cloetta's method requires an expensive apparatus, the author simplified it somewhat. Her method is a moist incineration by means of sulphuric acid. The incineration is repeated from three to five times until the remaining ash is white and no longer has an acid odor. The ash is combined with distilled water and the potassium content is then determined according to the method of Jendrassik and Szél. In tests on normal persons the author found that the potassium values vary in different persons, but she gained the impression that the normal values fluctuate between 16.8 and 21.45 mg. per hundred cubic centimeters. She also made tests on patients with fever and found that the potassium content of the blood serum was greatly increased during fever and decreased again after it subsided. Experiments on rabbits disclosed that, if fever is produced in normal animals, the potassium content of the blood serum becomes considerably increased. After the fever subsides, the potassium content becomes normal again, or it may even go below the initial value.

Studies on Poliomyelitis—Bastrup observed 120 hospital cases of poliomyelitis. The disease can usually be diagnosed during the preparalytic stage solely from the clinical symptoms, but the spinal fluid tests, especially those which determine the number of cells, and the albumin and globulin, are helpful. In discussing the differential diagnosis, he gives particular attention to the disorders which may present similar symptoms or meningeal symptoms: influenza, encephalitis and tuberculous,

purulent or serous meningitis. He calls attention to the similarity between preparalytic poliomyelitis and so-called benign idiopathic serous meningitis and suggests that probably some of the cases that are diagnosed as serous meningitis are really sporadic cases of preparalytic poliomyelitis. He warns against attaching too much differential diagnostic importance to the sugar determination in the spinal fluid. He criticizes the practical value of the usual measures taken to combat epidemics and discusses serum therapy. This therapy presupposes that in the beginning poliomyelitis is a general infection, which later on, in the preparalytic stage, betrays a tendency to advance toward the central nervous system. The experiments with monkeys merely argue in favor of a possible prophylactic effect on the paresis, but not a curative effect. Once the paresis is present, serum therapy seems to be useless. Of the patients observed by the author, thirty-two received this therapy, ten were treated with horse serum and twenty-two with convalescent serum. The horse serum had no effect whatever. It could not be established definitively that convalescent serum had a prophylactic effect against paresis, nor could it, on the other hand, be shown that it did not. Nevertheless, according to the observation of the author and a few other investigators, convalescent serum seems to influence the general condition in some cases, and the author thinks that this form of therapy deserves further trials. He suggests the alternate intravenous and intramuscular injection as the best method of administration of convalescent serum.

Cause of Death in Peptic Ulcer—Christiansen's report is based on twenty-one fatal cases of massive hemorrhage in peptic ulcer. Necropsy was done in sixteen of these cases, and in twelve cases it revealed erosion of fairly large arteries. The time that elapsed from the beginning of the hemorrhage until death varied between three and thirty days. As it is hardly possible that a patient may live for any number of hours with a continual arterial hemorrhage, it seems reasonable to conclude that the hemorrhage must have stopped sometime before death and, consequently, that the hemorrhage could not have been the cause of death in the strictest sense of the term. This applies in particular to the cases which might be designated as "late" deaths. In some of these cases, complicating and intercurrent disorders (perforation, pneumonia, embolism) may have constituted the cause of death. In a majority of the cases, however, the fatal outcome resulted from general exhaustion. This condition is characterized more by symptoms of intoxication than by symptoms of true anemia, and even in those cases in which arterial erosion could be demonstrated on necropsy the hemorrhage presumably had ceased sometime before death. The hypothesis is set forth that this general exhaustion is a condition of extrarenal hyperazotemia, which may be preceded and accompanied by achloruria, and that this condition may be treated successfully by the administration of sodium chloride. In contrast to other forms of uremia of gas-trogenic origin, uremia associated with massive hemorrhage in peptic ulcer develops insidiously and without vomiting. The theory is advanced that in these cases the hyperazotemia is a symptom of intoxication arising from absorption of toxic substances that are formed by bacterial decomposition of the blood stagnating in the intestinal canal, this intoxication is further aggravated by demineralization from excessive flushing of the organism by water.

SYPHILIS AND PREGNANCY

A CLINICAL STUDY OF 2150 CASES

CHAIRMAN'S ADDRESS

JAMES R. McCORD M.D.
ATLANTA, GA

The women in this study were all colored and each had a strongly positive blood Wassermann reaction during some period of pregnancy.

It has been said that studies of this sort are of local interest only and without value except for the colored race. It is true that the incidence of syphilis is much higher in the colored race, but the disastrous results of syphilis on pregnancy are the same in every language, creed and color.

The study shows, indisputably, the ravages of the disease on pregnancy, the wonderful results of efficient antepartum antisyphilitic therapy and the maternal safety of such treatment.

RESULTS OF PREVIOUS PREGNANCIES

The records of previous pregnancies of 826 of the 2150 women were studied. Pregnancy ended disastrously 1,369 times. It is probable that there were not as many term pregnancies as the figures indicate (table 1), because the information concerning the duration of pregnancy was obtained from the patient.

ANTEPARTUM THERAPY

The antepartum clinic was visited by 1,454 women one or more times. Blood for the Wassermann test was obtained at the first visit. During recent years the positive Wassermann reactions have been repeated. A Wassermann test was done at the time of labor on the 696 women who did not visit the antepartum clinic.

The fundamental principle on which all our antepartum therapy is based is the prevention of the disease in the baby. We make no effort to cure the disease in the mother. Antepartum treatment is mild but continuous. Strict adherence to this principle makes antepartum treatment safe for the mother.

Our treatment consists of the intravenous administration of 0.45 Gm of nearsphenamine and a mercurial injection. In most cases treatment was given weekly. For the past two years two injections have been given each week.

The 2,150 pregnancies were classified as term, premature, late abortion and early abortion. If the result of pregnancy was a stillborn baby or a baby that died in the hospital, pregnancy was considered disastrous. The outcome of pregnancy was disastrous in 633

women. This means that 29.4 per cent of the 2,150 women did not leave the hospital with a living baby (table 2). The increase in the percentage of term pregnancies, and the decrease in the percentage of premature pregnancies, late abortions and early abortions with an increased number of antepartum treatments is shown in a striking manner in table 3. In this table the number of disastrous pregnancies are correlated with the number of antepartum antisyphilitic treatments. This percentage varies from 49.4, when no treatment was received, to 5.4 per cent, when ten or more treatments were received. These figures indicate that the best results are obtained with ten or more antepartum treatments. Syphilis rarely waits until the end of pregnancy to reveal its disastrous effects.

TERM PREGNANCIES¹

There were 1,368 term pregnancies, 1,269 babies were born alive and discharged from the hospital (92.8 per cent). Seventy-three babies were stillborn and twenty-six died in the hospital (table 4). It is to be remembered that the term babies discharged alive did not all escape infection. As will be shown later (table 11), 11.4 per cent of the living term babies had positive cord Wassermann reactions. Of the ninety-nine women who had disastrous pregnancies, seventy-one, or 71.7 per cent, had not received treatment. Term pregnancies ended disastrously in 14.7 per cent of the 484 women who did not have treatment and in 3 per cent of the 261 who received good treatment. It is probable that the latency of the disease in the mother explains the high percentage of term babies that were discharged alive.

PREMATURE PREGNANCIES²

The relation between prematurity and antepartum treatment is shown in table 5. Five hundred and five pregnancies were classified as premature. Two hundred and forty-eight babies were born alive, 184 were stillborn and seventy-three died in the nursery. The women who had not received antepartum treatment gave birth to 57.6 per cent of the premature babies and those who had good treatment gave birth to only 7.1 per cent. Premature pregnancies ended disastrously in 65.6 per cent of the women receiving no treatment and in 19.4 per cent of those receiving good treatment.

These figures do not give a complete picture of the tragic results. Two hundred and forty-eight premature babies left the hospital alive. It was impossible to follow most of them. It is a conservative estimate to say that 50 per cent died within a few weeks.

LATE ABORTIONS³

There were 154 late abortions. Eighty-seven per cent of the women did not receive antepartum treat-

2 From seven to eight months from 1,500 to 2,500 Gm.

3 From five to six months, from 1,000 to 1,500 Gm.

ment Table 6 shows only one late abortion among those women who had more than six treatments. Of the 2,150 women in the study, 605 had six or more treatments. Only one late abortion occurred in this group (table 3). Not a single late abortion occurred among the 298 women in the study who received good treatment.

10 or more	298	87.6	12.1		0.3	5.4

EARLY ABORTIONS ⁴

One hundred and twenty-three women aborted early. Eighty-four and six tenths per cent of these did not have prenatal treatment. Table 7 shows the marked decrease of early abortions with increased antepartum treatment. Among the 605 women who had six or more treatments, there were but five early abortions (table 3). Only one early abortion occurred among the 298 women who received good treatment.

Increasing experience leads me to believe that maternal syphilis is probably a more frequent cause of early abortion than is now believed.

THE DEVASTATION OF SYPHILIS

The devastation of syphilis is further shown in table 8. Pregnancy ended prematurely 782 times. Of the 782 women, 67.6 per cent did not have antepartum antisyphilitic treatment. Nineteen and eight tenths per cent of these received poor treatment (fewer than six treatments). Pregnancy ended prematurely in only 4.7 per cent of the women who had good treatment (ten or more).

THE EFFECT OF ANTEPARTUM THERAPY ON THE MATERNAL WASSERMANN REACTION

One or two Wassermann tests were done on 1,257 women in the antepartum clinic and were repeated at the time of labor (table 9). Our experience is that of

others doing this work, that is, the Wassermann reaction seems as dependable during pregnancy as it is at any other time.

Of the 1,257 women, 273 received good treatment. The Wassermann reaction was negative at the time of labor in 77.3 per cent of these.

A negative Wassermann reaction during pregnancy, as at any other time, is not assurance that the patient does not have syphilis. There were ninety-five women with a negative clinic Wassermann reaction who did not receive antepartum treatment. The Wassermann test repeated at the time of labor on these women was positive. The results of the ninety-five pregnancies are of considerable interest (table 10). It is assumed that the disease was probably more or less latent in these women, yet pregnancy ended disastrously in 31.6 per cent.

THE CORD WASSERMANN REACTION

It has been repeatedly stated in the literature that the cord Wassermann reaction is of little or no value. An analysis of the cord Wassermann reactions on 1,372

have antepartum treatment and the mothers of 10 per cent received fewer than six treatments.

ROENTGENOGRAMS OF DEAD BABIES

Roentgen studies were made of the long bones of 329 dead babies (table 13). The changes that are believed pathognomonic of congenital syphilis were present in 205 babies (62.3 per cent). The mothers of 83.9 per cent of the syphilitic babies did not receive treatment, and 15.1 per cent of them received fewer than six treatments.

It should be emphasized that the organisms of syphilis were found in 61 per cent of the babies on whom a Levaditi stain was done, and that long bone changes were present in 62.3 per cent of those of whom a roentgen examination was made. This is not a

coincidence. The two groups do not represent the same babies. Both examinations were made of many of the babies but by no means all of them. This close percentage strengthens the belief that either method, properly done, is equally dependable in the diagnosis of congenital syphilis.

SYPHILIS AND SOME COMPLICATIONS OF PREGNANCY

The opinion is more or less widespread that one of the causes for the high maternal mortality of colored women is the high incidence of syphilis. The fact that there were but three deaths in this series of 2,150 women seems to refute this opinion. Sepsis was the cause of each death.

It is of interest that 16.6 per cent of the last 15,011 Wassermann tests from our clinic were positive. This is not the true incidence of syphilis in pregnant colored women, because many of the tests had been influenced by treatment in previous pregnancies.

Any systolic blood pressure of 135 or higher, is recorded as a hypertension. The incidence of hypertension in this study was 26.3 per cent. In our clinic,

the incidence of hypertension in women with a negative Wassermann reaction is just as high. I believe that syphilis, per se, has but little to do with the hypertensions of pregnancy.

Eclamptic convulsions occurred in sixteen women (0.74 per cent). This incidence is not high when the incidence of hypertension (26.3 per cent) is recalled.

Preeclampsia was diagnosed in 156 women, and 108 women were believed to have chronic nephritis.

CONCLUSIONS

As a result of my experience in this study, extending over a period of twelve years, I feel justified in forming the following conclusions:

1 Pregnancy does not affect the reliability of the Wassermann reaction.

2 This test should be a routine part of antepartum care.

3 Regardless of the activity of the disease, sufficient antepartum antisyphilitic treatment assures the woman a syphilis-free baby in 95 per cent of the cases.

4 The best results will be obtained with ten or more treatments.

5 Treatment should be mild but continuous and should not be controlled by the Wassermann reaction.

6 The concurrent use of arsenic and a heavy metal has worked well in our hands.

7 Such therapy seems to be safe for the mother.

8 In the vast majority of cases, a strongly positive cord Wassermann test, properly done, means that the baby has congenital syphilis. A negative cord Wassermann reaction is of little value in the diagnosis of congenital syphilis.

9 The characteristic picture of osteochondritis of the long bones is pathognomonic of congenital syphilis.

10 There seems to be no condition in medicine that returns such huge dividends in life and health with such a small output of energy and money as that seen in the prevention of congenital syphilis.

50 Armstrong Street

STREPTOCOCCIC MENINGITIS

REPORT OF CASE WITH RECOVERY

HARRY J. GRAY, MD

NEWINGTON, CONN.

Streptococcic meningitis has exacted an exceedingly high mortality. Most of the cases have been handled by otologists, as the incidence secondary to otitis media has prevailed in the larger proportion of all reported cases.

Thus far, the mortality rate, approximated from meager figures, appears to be over 97 per cent. Careful search of the literature reveals but sixty-six reported cases of recovery since 1901, including the one here reported. In reviewing the literature, one is impressed by the multiplicity and lack of correlated ideas as to the handling of this disease. Overzealousness has, to a considerable degree, resulted in the low percentage of cures. Fortunately, the number of cases of streptococcic meningitis is relatively small.

The majority of all streptococcic meningitis cases have as their source a purulent otitis media. I am aware that a purulent condition of the ear may exist coincidentally with a meningitis and the two be etiologically different. Therefore, it is necessary to find the same kind of organisms in the spinal fluid as in the ear to state that the meningitis is secondary to an otitis media.

At the Cook County Hospital in Chicago over a period of ten years (from 1911 to 1920) there were found only sixty-three cases of otitis out of a total of 1,188 cases of meningitis. There were 1,254 cases of suppurating ears, and the 1,188 cases were of that group. Fourteen of the 1,188 were due to accessory nasal sinus disease. Thus, it is seen that in some of the cases the otitic suppuration had no etiologic relationship to the meningitis. Eight cases showed streptococci on culture of the spinal fluid, approximately 0.7 per cent of the total number of meningitis cases. The other sources of origin were syphilitic, 6 per cent, tuberculous, 25 per cent, epidemic cerebrospinal, 48 per cent, and other infectious types—of which the streptococcic was a small part, and those of undetermined origin—20 per cent. From the foregoing figures, it is seen that the number of meningitis cases of streptococcic origin is relatively small. The meningitides should be separated into etiologic groups and a more definite and common plan of therapy inaugurated accordingly.

Kopetzky¹ classified the otitic meningitides and gave a summary of the spinal fluid characteristics in the various types: (1) protective meningitis (meningitis sympathica) and (2) suppurative meningitis (dangerous). Under type 2, he names two types: (1) fulminating and (2) exudative. When his classification is used with the spinal fluid changes, the differential diagnosis may be made a better prognosis given, the type of therapy planned and an effort made to carry it out.

The one common action agreed on by all is the complete eradication of the primary focus of infection, if possible, at the earliest moment. In cases in which more radical procedures have been used there have been fewer recoveries.

General surgeons, in the past, incised streptococcic foci and in most instances made numerous incisions into contiguous tissues with resultant spread of the infection.

From the United States Veterans Administration Facility

and greater mortality. Since a more conservative therapy by serums, numerous blood transfusions, local fomentations and conservation of the patient's strength by supportive measures has become the rule, more cures have been secured. Blood transfusions, even when the cell counts and hemoglobin are practically normal, have been given the credit of producing cures.

Were one to resort to extreme surgical measures (other than removal of the initial focus or foci) in the treatment of streptococcic meningitis, would one not break down protective barriers, remove the antibodies already built up and spread the infection to otherwise unaffected parts? The literature is abundantly witness to that fact. There are more frequent cures in cases in which more conservatism has been the rule. There are records of cases that have presented so-called spontaneous cures which, undoubtedly, have been due to the active protective reactions on the part of the host.

Spinal puncture with slow removal of a small quantity of spinal fluid for pressure, cell count, bacterial, copper reduction and other determinations is necessary and without harm in most cases. What is the result, however, when large amounts are taken at frequent intervals, in cases in which it is not under excessive pressure, with the idea of draining away infection products? It would be as reasonable to drain away the blood in septicemia. It is putting a demand on structures that form the fluid and is liable to lead to their exhaustion and it allows greater influx of bacteria if the initial focus has not been eradicated.

Experiments have failed to show any appreciable results from the injection of serums, drugs and chemicals into the spinal canal in streptococcic meningitis. Canuyl, Tassowatz and Wild² stress the beneficial effect of Vincent's streptococcus antiserum combined with blood transfusions and formation of a fixation abscess. They state that it is not necessary to inject the serum into the spinal canal, intravenous injections may suffice. They favor daily spinal punctures. However, the procedures followed in the cured cases show that unless there are definite signs of increased intracranial pressure the spinal fluid should be left alone as much as possible. New blood from donors, donors with acquired immunity built up by working in hospitals, should be given the patient in frequent transfusions.

Fleischmann,³ in experiments in the chemotherapy of meningitis, found that preparations given by the spinal route are not effective. He believes that disinfection of the meninges through the blood is possible, and that the plexus is permeable by drugs given intravenously. He showed this to be true in that, when 100 cc of anti-streptococcus serum was given intravenously, it could be demonstrated in the spinal fluid after from twelve to twenty-four hours in concentrations not much less than that in the blood. He later demonstrated that the same is true of agents used for chemotherapeutic purposes in cases of meningitis, while in normal cases even fatal doses failed to show in the spinal fluid.

Kolmer⁴ shows that intracarotid injections are simple and safe, that intense concentration of the medicament occurs in the meninges, and that encouraging results have been observed in that method of treatment of severe pneumococcic and streptococcic meningitis. In reviewing the literature, even the excessive trauma of

cutting down on the carotids appears not to be necessary, as sufficient concentration may be had by the usual intravenous route. I am reporting here a case of recovery in which there were no residuals, wherein the treatment was very conservative. Transfusions and medication were given by the usual intravenous route.

REPORT OF CASE

A white man, aged 34, weighing 150 pounds (68 Kg.), a laborer, admitted to the Veterans' Administration Facility, Jan. 26, 1934, complained of severe headache, fever and stiffness of the neck. He had a perforated left ear drum from a shell explosion during the World War, and the ear had discharged pus almost continuously since the date of injury. The longest period of freedom from discharge was about six or seven months. Tonsillectomy had been done about ten years before. The patient could not recall any serious illness. Two weeks before admission he noted extreme headache and stiffness of the neck muscles, but he was able to be up and about for two days, during which time he felt fine. January 24 he noted a return of the stiffness of the neck, accompanied by severe headache and fever. On admission the temperature was 101 F., pulse 80. He appeared extremely ill.

On examination the pupils were equal and regular and reacted to light and in accommodation. There was no nystagmus, ptosis or lag. The media and fundi were normal.

The tympanic membrane of the right ear was intact, slightly dull and moderately retracted. The spoken voice could be heard at 2 feet. Bone conduction was normal. Records showed that hearing had been in this state for some years past. The left ear presented a moderate sized central perforation of the tympanic membrane with seropurulent discharge, nonpulsating. There was no pain on pressure over the mastoids but the left was shaded to transillumination. There was a subjective feeling of deep pain in the area of the left mastoid. Records showed that there had been no hearing of the spoken voice with the left ear for years. Bone conduction was absent.

Transillumination of the sinuses was clear.

The neck muscles were rigid, the neck moved from side to side with great difficulty and pain.

The heart, lungs, abdomen, genitalia and extremities were normal. Knee jerks were absent, Kernig's, the cremasteric and the plantar reflex were present.

A spinal puncture was done, January 26. The fluid was under increased pressure and was opaque, the smear showed gram-positive extracellular cocci—single and in pairs. No intracellular or gram-negative cocci were found. There was no reaction with Neufeld pneumococcus serums types 1, 2 or 3. Many polymorphonuclears and few lymphocytes were found in the smear.

Gram-positive cocci were found in smears of the ear as in the spinal fluid and throat, singly and in pairs.

Cultures of spinal fluid showed alpha hemolytic streptococci, verified by the Connecticut State Bureau of Laboratories. Cultures of ear discharge showed the same.

Blood cultures were negative for any growth at any time.

Roentgen examination of the right mastoid showed large cells of the pneumatic type, with the walls intact. There was dense opacity of the entire left mastoid with complete occlusion of all the cells and no evidence of any air. The density was most marked in the periantral cells and the zygomatic process.

The Wassermann reaction was negative.

Blood counts revealed a normal number of erythrocytes, leukocytes varied from 7,300 up to 21,400, hemoglobin was from 95 per cent to 100 per cent.

The blood type belonged to group O (NRC) or IV Moss.

Treatment was immediately inaugurated. 95 per cent grain alcohol being used in the left ear, an ice cap was applied to the head, and codeine one-half grain (0.06 Gm.) given every six hours if necessary for pain. At 8 p. m. the temperature was 102.4 F. The second day, headache was less in the morning and alcohol drops in the ear were given with greater frequency, every two hours. The minimum temperature was 101.2 F., the

⁴ Kolmer, J. A. *Laryngoscope* 42: 12-33 (Jan.) 1932.

maximum 103 F. On the third day, January 28, the morning temperature was 101.2 F. A blood transfusion of 500 cc by the citrate method was given, followed by a chill of short duration, the temperature rising to 103.8. The patient felt much better. Liquids were forced, and catharsis and general supportive measures were administered. The patient continued to improve slowly with a temperature curve similar to lysis in pneumonia, to normal, February 4.

February 5 the ear discharge became much diminished, headache became very severe, and the temperature rose to 99 F, rigidity of the neck increased and the patient seemed somewhat confused. There was no projectile vomiting at any time.

February 6, a blood transfusion was given followed by elevation of temperature to 100.8 F later falling to normal. The patient felt much better. Transfusion was decided on preliminary to operation. The ear discharge, as stated, had become reduced in quantity and changed to a serous nature while on February 6 the quantity increased, becoming seropurulent again, and pulsating in character. I considered that, since the patient had extreme headache and more rigidity with rising temperature before transfusion, and since the character of the discharge had changed, there was pus beneath the external sclerotic plate

of the mastoid with a channel into the cranial cavity, and that obstruction to external drainage was forcing purulent material inward.

February 7, a simple mastoidectomy was performed on the left. The antrum was found full of granulations and seropurulent material. A large mastoid cell, also, full of granulations and seropurulent material, was present, opening into the antrum just external and inferior to it. A small fistulous tract led directly upward from the antrum to and through the tegmen, which was eradicated and the dura exposed as widely as possible. All granulations were removed from the antrum and the aditus. The wound was left open after plain gauze drains were inserted and dry dressing was applied. The mastoid otherwise was sclerosed to the nth degree.

Following the operation, the patient had less pain and rigidity. He had a gradual abating septic temperature until February 18, at which time it became normal. Another transfusion was given, February 16.

From the date of operation, at which time he was given intravenous dextrose following the operation, daily high colonic irrigations were given, the drain in the ear was kept renewed and moistened by 95 per cent grain alcohol, frequent saline

purges were given, fluids were forced 5 cc. of methenamine was administered intravenously every day for three days

The dressing was not changed until four days following operation, at which time drainage was found to be good, and patient had no complaint.

The patient able to be out of bed March 5

Daily cleansing of the ear was carried out, and from March 5 alcohol was used in the ear only three times daily. By May 22 the mastoid incision was healed, the ear was completely dry, and the patient had gained in weight and was feeling well. Examination by the neuropsychiatrist revealed no residuals mentally or neurologically.

More interest should be shown in such a fatal disease, and cases should all be reported whether there has been recovery or not. In that manner more rational therapy could be inaugurated and more accurate figures secured for statistical information. There have been cases cured that have never been reported, which would have been of greater value to the profession had they been reported with complete data.

It will be noted from the accompanying table of reported cures that there has been a number of cases of complicating otitis. Most of the reported cases were treated conservatively.

SUMMARY

Streptococcic meningitis is usually a fatal disease with but sixty-six reported cases of recovery over a period of thirty-four years.

Treatment of most recovered cases has been more conservative than the generally published regimen and consists principally of eradication of the initial focus, spinal taps, intraspinal and intravenous injections of serums and blood transfusions.

The case here reported was treated conservatively, and it would be difficult to state the definite cause of recovery. It is the opinion, however, that maintaining the physiologic balance, as nearly as possible, had more to do with recovery than any other procedure.

INTRANASAL OPERATION FOR CHRONIC MAXILLARY SINUSITIS

END RESULTS IN TWO HUNDRED CASES IN
WHICH THE PRINCIPLES OF KÜSTER
WERE EMPLOYED

HENRY L. WILLIAMS, M.D.
ROCHESTER, MINN.

In his discussion of the treatment of otitic sepsis, Ballance¹ remarked

Want of agreement among serious workers about a grave question of surgical treatment arises either from the lumping together of clinical conditions having an essentially different pathological basis or from essential pathological conditions not being clearly understood. All true and lasting surgical practice is based upon pathology, and when once the pathology of an affection is clearly appreciated divergence of view as to its treatment ought to disappear.

It is our opinion that basic surgical principles adequate to the cure of chronic suppurative disease of the paranasal sinuses were laid down by Kuster² fifty years ago, and that divergence in views as to the surgical treatment of this disease ought therefore to disappear. Any further advance in treatment should be in the direction of a more refined differential diagnosis and proper selection of cases and in the field of nonsurgical treatment.

It might be useful in evaluating these principles to trace the history of their development. To Meibom³ in 1718 is attributed the first attempt to cure suppuration in the maxillary sinus by operative intervention; he removed a tooth and lavaged the antrum through the fistula. Cowper and others later advocated the same treatment. This procedure was discarded because of the frequent necessity of sacrificing a sound tooth, and particularly because in only a few cases were symptoms relieved.

Lamorier⁴ and Desault⁵ advised puncture and lavage through the canine fossa, but this treatment was discarded because of the paucity of favorable results. Jourdan⁶ enlarged the natural ostium in an attempt to secure drainage along normal pathways, and Zuckerkandl⁷ in 1882 advised entering the maxillary sinus behind and below the infundibulum. These two approaches were discarded because of the severe bleeding encountered from the anterior lateral branch of the sphenoplatine artery, but more especially because of the frequency with which the orbit was entered. Mikulicz⁸ in 1886 advised opening the antrum through the inferior meatus, in order to retain as nearly as possible the normal pathway of antral discharge and at the same time avoid the dangers of Zuckerkandl's approach. He devised a trocar, later modified by Wilhelmski, with which to perforate the lateral nasal wall, and a curved cannula with which to carry out postoperative lavage, using a solution of boric acid.

In 1889 Küster published his fundamental paper, "The Basic Principles of the Treatment of Suppuration

in Rigid Walled Cavities." He took the maxillary sinus as the example of a completely rigid walled cavity with a lining of mucous membrane. He established as his principles of treatment an opening into the sinus large enough to allow inspection of the interior, and the removal of diseased portions of the membrane, polypi and sequestrums, and the establishment of a permanent fistula to afford unobstructed drainage. It is on these principles that all later sinus surgery has been based. He chose as his route of approach the canine fossa, making an opening from the pyriform process to the region of the first molar, and maintained the patency of the opening by suturing the mucous membrane of the antrum to the mucous membrane of the gingivobuccal groove.

In 1893 Caldwell,⁹ because of the extreme difficulty encountered in preventing reinfection of the antrum through the mouth with a permanent fistula present in the canine fossa, opened the antrum through the canine fossa, removed diseased tissue as advocated by Küster, and then made a permanent counter opening into the inferior meatus and allowed the opening in the canine fossa to heal. Because this method of surgical treatment met the requirements of Küster without the disadvantage of a permanent fistula into the mouth, and because it combined the advantage of a physiologically normal pathway of discharge, as advocated by Mikulicz, it gained immediate popularity and almost supplanted all other methods of surgical treatment of suppurative disease of the maxillary sinus. The Mikulicz operation was relegated to the position of an accessory to lavage of thick walled antrums because adequate exposure to remove diseased tissue and a permanent opening for drainage were not secured by the original technic.

Luc¹⁰ in 1897 described a similar technic, which has caused his name to be linked with Caldwell's, although his paper was published four years later. In 1903 Luc¹¹ advocated a large primary opening through the canine fossa, complete removal of the lining mucous membrane of the antrum, and a counter opening into the nasal chamber. He said

My double aim while performing the operation in question is to make two large bony resections. The one at the expense of the anterior wall of the sinus in order to obtain a wide but transitory communication between the sinus and the mouth and to remove completely the pus and diseased mucous membrane, the other at the expense of the internal or nasal wall of the sinus in order to create a wide and permanent communication between the antrum and the nasal fossa. This latter resection, which requires simultaneous ablation of the greater part of the middle and inferior turbinals, is greatly facilitated by the introduction of the little finger into the nostril, which enables the surgeon to avoid any lesion of the septum and to ascertain that the free communication desirable has been obtained and that no fragments of the turbinal mucosa likely to be in the way of the further drainage has escaped the cutting forceps. A considerable opening, not amounting to less than the third part of the wall at whose expense it is made, thus making the maxillary a sort of prolongation of the corresponding nasal fossa, [is fashioned]

In this paper he suggested, and this was apparently the first time it was suggested, complete removal of the lining membrane.

In 1927 Hempstead⁸ described a technic of approach through the inferior meatus that met the requirements of Kuster without sacrificing any of the functioning tissue of the nose and avoided the more troublesome approach through the canine fossa. He advocated fracturing the inferior turbinate bone upward so as to expose freely the lateral wall beneath it. An opening was then made into the antrum large enough to afford easy inspection of all the lining mucous membrane except that of the anterior wall. This area could be inspected with the aid of a mirror. Any grossly diseased tissue was removed with a curet. After-care was by the dry method. This technic has been followed in the present series of cases.

The two methods that fulfil the surgical principles of Küster are the Caldwell technic and Hempstead's modification of the Mikulicz technic. There can be no question that the exposure in the Caldwell technic is somewhat superior, so this approach is reserved for those cases in which there is a suspicion of malignancy, evidence of sequestration, and for that small percentage of cases in which sufficiently good removal of diseased tissue has not been accomplished by the intranasal operation. Owing to the fact that the Mikulicz technic offers a greater rapidity of operation and ease of approach, with avoidance of the postoperative neuralgia sometimes seen with disturbance of the infra-orbital nerve, and owing to the fact that there is a less prolonged stay in the hospital with postoperative results equally good in our hands we have adopted it at the Mayo Clinic as the routine treatment, reserving the Caldwell approach for types of cases outlined before.

The question which is of the greatest moment in considering the value of the Mikulicz technic is the contribution of Luc, that is to say, the extent to which the lining mucous membrane of the sinus should be removed, or, more particularly, the meaning of "diseased membrane," as of course complete removal of the mucoperiosteal lining of the sinus in this approach is impossible.

Emerson⁹ stated that antrums with chronic atrophic changes in the mucous membrane were the most fertile source of systemic infection, he advocated entire removal of the lining membrane as the only adequate treatment. Kistner¹⁰ said "Hyperplasia in a sinus mucosa is one of the usual structural changes found in chronic latent or nonpurulent sinusitis. In patients in whom this type of sinusitis was associated with a systemic disease we found these tissues to contain pathogenic organisms." The attempt is made to separate this type of disease from ordinary chronic suppuration, so the application of these quotations to the type of case cited in this paper may not be exact.

Ferris Smith¹¹ however, is less cautious in his statements and said "It is obvious to every observer that infected lining membrane presenting marked chronic inflammation with cystic glandular degeneration and glandular hyperplasia, marked fibrosis with chronic infection, abscess formation in its various stages, chronic periostitis and other changes can never return to normal. In an extensive experience I have never failed to find bacteria in these chronically diseased sinus linings. They are common in the subepithelial areas in

the early chronic cases and are always found about the glands and vessels and in the reticular spaces in the old cases." He therefore, advocated removal of the lining membrane of the sinus with meticulous care.

Kistner, inferentially to add further support to the practice of complete removal of the mucoperiosteal lining of the sinus, maintained that the normal submucosa did not reconstitute itself after removal to furnish a lurking place for the pathogenic organisms that he found present. McGregor,¹² on the other hand, found that through a process of metaplasia the subepithelial fibrous tissue developed a submucosa in all respects similar to the normal, except that in cases wherein excessive granulation tissue had formed postoperatively it was likely to mean a thicker stroma. He reported a case in which a person with severe diabetes died sixteen days after operation of streptococcal septicaemia, colonies of organisms were found in the subepithelial tissue. He added "This is the only case in which I have been able satisfactorily to demonstrate organisms in the lining of the antrum although I look for them as a routine measure." Ross¹³ came to the conclusion that "actual bacterial invasion of the nasal mucous membrane prior to operation does not appear to occur from the evidence at hand." Such diametrically opposed conclusions mean that faulty observation occurred on one side or the other.

The articles of McGregor and Ross, however, produce no convincing reasons why the lining membrane should ever have been removed at all and apparently support the practice on grounds that no harm is done.

Fenton and Larsell¹⁴ found that the histiocytes in the subepithelial tissues are primarily concerned with the protection of the organism against invading bacteria, and also that chlorides have an inhibiting effect on their action. These observations would argue for the retention of a normal lining mucous membrane and avoidance of saline solutions in the treatment of sinusitis. Lawson¹⁵ stated that "actual secondary or subinfections are not seen resulting from acute and chronic disorders of sinus membrane with the frequency that theoretically should hold in view of the purulent character and amount of pathological change."

That systemic effects secondary to suppurative disease of the sinuses are probably rare was demonstrated by Anderson¹⁶ in that he failed to find evidence of such effects in 400 consecutive cases of chronic sinusitis. This tends to support the contention that bacterial invasion of the submucosa is uncommon.

French¹⁷ was of the opinion that "the chances for a good result are better to leave all mucosa possible." Hilding¹⁸ found in dogs that removal of the lining membrane of the frontal sinus was followed by the formation of bands of scar tissue which inhibited free drainage of the sinus, and that epithelium often failed to cover the scar.

Gorham and Bacher¹⁹ stated that from three to five months after complete removal of the lining membrane of the antrum in an unstated number of cases "there were a few small septums that formed incomplete pockets in the membrane" Mosher,²⁰ in his discussion of this paper, was of the opinion that this was the explanation of some of the unsatisfactory results he had observed in this type of operation due to the formation of bands of scar tissue Lewis²¹ said

It has been observed in dogs that excision of the antral wall and removal of the mucosa is followed by complete return to normal of the tissue and structures involved Compare this with your own observations of radical operations on human beings, or with the statements of many observers, whose findings include cicatricial basement membrane, squamous and cuboidal epithelium, vestiges of glands, general fibrotic changes and more or less complete obliteration of the stomata and subepithelial lacunae

It would seem from the foregoing review that the preponderance of evidence is in favor of removing only the obviously diseased portions of the lining membrane of the sinus The question of the presence or absence of bacteria in the submucosa of the sinus apparently needs clarification

Articles based on experience in using the Mikulicz type of operation are very few, as the Caldwell operation has almost supplanted it In 1921 Barlow²² reported the results in 100 cases, finding that 47 per cent of the patients were cured He further stated that, in cases in which the condition did not clear up, a sufficiently large intranasal opening had not been made at the first operation Tucker²³ reported 673 cases of chronic maxillary sinusitis in which patients were operated on by Hempstead's modification of the Mikulicz technic, and while he did not so expressly state, he implied that a cure was obtained in all but six cases Stevenson²⁴ reported 198 cases of chronic maxillary sinusitis in which the intranasal window operation was done in all but twenty-one It was necessary to do the Caldwell type of operation in five cases following primary window resection Stevenson found that complete recovery followed in all but nine cases

Buckley²⁵ in 1934 stated that "the intranasal operation when well done offers in a fairly large percentage of cases good results, but that result cannot be expected by simply making an opening in the antrum" Goodyear²⁶ stated (1934) that, since 1927, he had been increasingly interested in the results obtained by the intranasal operation, and he described a technic similar in all important respects to that described by Hempstead in 1927 He found, after many Caldwell-Luc operations, that the cavity of the antrum filled with a thick fibrous tissue, and that in some cases pocketing and reinfection occurred He said "Following the intranasal operation I have not been able to find any cases

in which this extreme thickening of tissue occurs, probably because the lining membrane has not been removed" He said further "I was particularly impressed with the fact that when only fair or poor results were obtained the opening was usually correspondingly bad"

This review of postoperative results has been limited to cases of chronic suppurative disease of the maxillary sinus because the simplicity of its structure makes the application of the surgical principles adopted less technically difficult and the diagnosis of chronic suppurative disease more certain If these surgical principles are applicable to the cure of maxillary sinusitis, it should follow that they could be applied to suppurative disease of all the other sinuses because of similarity in structure and physiology As a matter of fact, in 1893 Jansen²⁷ applied these surgical principles to the treatment of suppuration in all the paranasal sinuses, and he described the operative technic later popularized in this country by Lynch,²⁸ Sewall,²⁸ Ferris Smith and others

Two hundred consecutive cases of chronic suppurative disease of the maxillary sinus in which patients were operated on by various members of the staff during the year 1926 have been selected for the present study because sufficient time should have elapsed to judge whether or not any good results obtained might be permanent As the gage of chronicity, no case has been selected in which continuous symptoms have not been present for a year or more Although only a small proportion of these cases were investigated for the presence of specific hypersensitiveness, such cases have been almost eliminated by confining consideration to those cases in which the maxillary sinus alone was involved

Questionnaires have been sent these patients for detail as to whether or not their symptoms were relieved, and especially as to whether any further operations on the sinuses have been found necessary Those patients whom it was possible to reexamine in the past two years are considered as a separate group

In the group of cases in which an opportunity was afforded to observe the condition of the antrum after a lapse of from seven to eight years, a total of 115 operations was performed on seventy-seven patients In thirty-one of these cases the operation was bilateral, and in six cases subsequent operative procedures were found necessary In forty-five cases, or 58.4 per cent of the total, gross changes, such as infected granulation tissue or polypoid degeneration of the mucous membrane, were found in one or both antrums

In this group of seventy-seven cases it was found that in eleven, or 14.3 per cent, the results were for one reason or another unsatisfactory Of the patients, one was completely cured from the clinical standpoint but subjectively was not relieved or was worse, and five returned in from six months to a year with recurrence due to failure to secure a large enough window at the first operation, these patients were again operated on by the intranasal route and subsequently remained well One patient returned after two years without relief of symptoms and it was found that the preoperative investigation had been defective and that infection in a frontal sinus had maintained the disease in the antrum The frontal sinus was drained by the intranasal route and the patient has remained well

28 Quoted by Smith.

Of the absolute failures, in one case the patient had chronic bilateral bronchiectasis and the antrums remained infected despite an apparently adequate operation, and in another the patient returned with the window closed but with absence of any suggestion of infection present in the antrum. The latter case would tend to cast discredit on the assumption that permanent drainage must be established to secure a cure, but it has been our experience at the clinic in a much more extended series of cases that the cause of failure is usually an inadequate window. In the last case in which cure was not obtained postoperative hemorrhage necessitated packing, following which fever developed (temperature 103 F) and considerable pain in the side of the head. The antrum became completely dry, but the patient had recurrence of pain and fever with colds. On investigation, chronic sphenoiditis and posterior ethmoiditis were found on the side that had been operated on. Symptoms could be regularly relieved by canalizing the sphenoid and sucking out the infected contents. It was thought that the sphenoiditis resulted from the packing of the nasal chamber.

Two other patients for whom the Caldwell operation had been advised elsewhere returned without relief of symptoms. They had both been treated by antral lavage since leaving the clinic, and on termination of this type of treatment the condition had immediately cleared up and they had had no subsequent symptoms. These cases are not counted as failures but are included in the list of unsatisfactory results.

In the group of seventy-seven patients who have been observed subsequently it was found that for 85.8 per cent the results were completely satisfactory but that eventual cure was accomplished for 92.3 per cent of them.

Of the remaining 123 who were not seen subsequent to operation, 104 reported that they had no symptoms suggesting sinus disease. In this group of cases there were seventy-three, or 59.3 per cent, in which there were such gross changes as polypoid degeneration and infected granulation tissue, this tissue was removed by the curet. In twenty-seven cases bilateral operation was performed, making a total of 150 operations in 123 cases. It might also be of interest to note that in fifty-two, or 25.5 per cent, of the 200 cases the infection in the antrum could clearly be attributed to extension of the infection from an apical abscess. A primary apical abscess was not noted in any of the cases in which bilateral operation was performed.

Of the nineteen patients for whom results were not satisfactory, four reported unmistakable symptoms of specific hypersensitiveness, and I am inclined to attribute failure of the operation to this cause. One patient reported a definite but gradual improvement in symptoms since operation, and I believe that this is a gradual loss of sensitivity and that the patient is probably allergic. Two patients had bronchiectasis, and not only were the thoracic symptoms not relieved but there was no improvement in the symptoms of sinusitis, one of these patients reported relief of nasal symptoms but noted no relief as far as his cough and expectoration were concerned. One patient's continuing symptoms, according to a letter from his local physician, were due to involvement of the frontal sinus, an instance of incomplete investigation. In another case in which a choanal polyp was removed the patient was well until two years ago but since then has had a 'continuous cold', the probabilities are that in this case there has been recurrence of the polyp. One patient with severe

diabetes and ozena who was operated on for elimination of foci of infection reported no improvement in symptoms, as was to be expected. This patient died in a diabetic coma two years after the operation. Although this patient failed to survive, it was thought that exclusion of this case from the tabulation on this account would be unfair.

Another patient is included in the list of unsatisfactory results because of the development of a dangerous complication, osteomyelitis of the superior maxilla. He recovered after a somewhat stormy convalescence, however, and has been well since. The condition of another patient was satisfactory on the side operated on but polyp had to be removed subsequently from the opposite side, undoubtedly a more careful examination would have revealed the presence of disease there. One patient reported that the alveolar fistula in the upper jaw had remained open and that he was practicing lavage of the antrum twice daily. A second patient reported that the fistula into the antrum had failed to close and that symptoms had persisted until plastic closure was done a year later, since then he has been free of symptoms, which indicates the necessity of preventing communication with the oral cavity. One patient obtained no improvement in symptoms until a Caldwell-Luc operation was done elsewhere, since that time the nasal symptoms have disappeared and a chronic arthritis, of which she complained, has been much improved. Finally, four patients reported continuance of symptoms for which no probable cause could be ascribed.

SUMMARY

For the group reached by questionnaire, only nineteen out of 123, or 15.4 per cent, obtained unsatisfactory results, in other words, combining the figures in the two groups, 84.6 per cent received complete symptomatic relief.

In analyzing the causes for dissatisfaction in the whole group of 200 patients, it was found that in seven cases the probable error of failing to diagnose the presence of specific hypersensitiveness was the determining factor. In four cases bronchiectasis was present and, although this number is too small from which to draw conclusions, it is suggested that bronchiectasis may be a factor in producing the sinusitis rather than the reverse. In two cases postoperative complications interfered with a good result, in one case osteomyelitis of the maxilla, in the other, sphenoiditis. In six cases closure of the intranasal window resulted in failure, and in four cases in which the patients' replies did not furnish sufficient data to justify conclusions failure probably resulted from the same cause. In two cases misdirected therapeutic efforts were the direct cause of continuance of symptoms, and in two others inadequate investigation failed to reveal the presence of a frontal sinusitis which maintained the infection in the antrum. In two cases failure to close a fistula from the alveolus to the antrum was apparently the cause of the difficulty, and in one case in which bilateral intranasal windows failed to relieve the nasal symptoms, bilateral Caldwell-Luc operations elsewhere eliminated such symptoms and apparently also caused marked improvement in arthritis from which the patient suffered.

CONCLUSIONS

- 1 The surgical principles laid down by Küster are sound and accomplish the desired result.
- 2 Hempstead's modifications of the Mikulicz and the Caldwell operations meet these requirements.

3 Failure to remove the mucoperiosteal lining of the sinus does not militate against a good result

4 Good results of the operation depend on securing an adequate and permanent opening for drainage and on removal of diseased membrane

5 Bad results are caused by failure to secure adequate drainage, incomplete investigation, failure in diagnosis, and poor selection of cases

6 Cure can be obtained in about 80 per cent of cases of chronic maxillary sinusitis in which operation is by the intranasal route, as was evidenced by this study of 200 cases

7 It is apparent, therefore, that the intranasal operation in the majority of cases gives such a satisfactory result that except in exceptional cases it should be the operation of choice

THE ACTION OF MERCUROCHROME AND OTHER DRUGS

ON NORMAL HUMAN SKIN AND IN
INFECTED WOUNDS

JUSTINA H. HILL, M.S.
BALTIMORE

To be worthy of clinical use any antiseptic must be able to survive severe criticism and to find its true level on a factual basis, confirmed by the studies of at least two independent groups of observers. Quite aside from fallacies arising from assumptions based on analogy, and from the personal equation, the problem of evaluating any antiseptic, especially one used in several fields, is extremely complex, because of the many factors involved. Unintentional errors of technic and of reasoning are to be found in most articles dealing with this highly specialized field within a field, in which the pitfalls are not always obvious even to the experienced worker. However, probably the chief merit of such a controversy is the instigation of further research. This may be of value not only for the drug or drugs in question but also in relation to the whole problem of antiseptics, by the reiteration of certain extrinsic limitations of the action of all drugs and by the introduction of new or improved methods for their evaluation.

The scope of this paper is confined to the presentation of additional material in regard to the bactericidal and bacteriostatic action of mercurochrome and other drugs on skin and in wounds. This involves certain carefully limited comparisons and the use of new methods. No attempt is made at this time to review the literature, but the subject matter is limited to new material for which I am personally responsible.

PART I. SKIN TESTS

There are no standard methods for determination of the bacteriostatic and bactericidal action of drugs on the skin. For short time bactericidal action a method of taking cultures either of the surface of the skin or of skin scrapings has been used with results sufficiently contradictory to indicate the inaccuracy of the method and the vitally important need of its rigid control and further refinement. By the application of massive cultures to animal skin¹ it has been shown that no anti-

septic should be relied on to sterilize skin thus heavily infected. Similarly, in long series of cultures from human skin¹ it has been shown that, while marked action is obtained with drugs acting on normal flora, this action is not invariable. It would require a long series of experiments and a most critical analysis of the technic employed to convince one that any drug now available always sterilizes human skin. A prompt reduction of the number of bacteria, bacteriostatic action and many actual sterilizations from a number of drugs now in use may be expected, but there is no basis for any conclusion that sterilization is always the rule. Certainly any drug proposed for use for preoperative skin sterilization should be described with a realization of this limitation.

There has been even less attempt to formulate standard methods for the much neglected study of the bacteriostatic action of drugs on skin. The finger-tip method, originally used to test the action of normal skin,² offers a possible basis for this. At least it is superior to two other methods I have tried, first that of von Oettingen³ with excised, refrigerated human skin, which I could not confirm and, second, my own method of applying cultures directly to the skin (series VII).

Condensed summaries are given here of recent experiments that show conclusively that both the aqueous and the alcoholic 2 per cent solutions of mercurochrome are bactericidal and bacteriostatic on human skin. Because of their different behavior and uses, it is necessary to differentiate the two types of solutions, first, the aqueous 1 or 2 per cent solutions for use on mucous surfaces and in wounds, and, second, the 2 per cent solution in 35 per cent water, 55 per cent alcohol and 10 per cent acetone, hereafter to be referred to as tincture of mercurochrome, which is used as a preoperative skin disinfectant. There is reason to believe, as will be shown later, that some aqueous solutions have definite advantages over tinctures for use in wounds and demonstration of their bacteriostatic and bactericidal action on surrounding skin is of value. On the other hand, I do not believe that an aqueous solution of any drug should be used for preoperative skin disinfection. For these reasons it is necessary to study both types of solutions and to avoid generalizations that do not take these points into consideration.

The finger-tip method, used in most of these tests, consists essentially of application of the drug to clean finger tips, by means of saturated cotton swabs, letting the fingers dry in air and from three minutes to twelve hours later applying the ball of the treated finger lightly and steadily for from one to five minutes to the surface of an agar plate, deeply seeded with the test organism. After twenty-four hours of incubation at 37.5 C., the maximum dimensions of the areas of bacteriostasis, as represented by clear zones, and of the actual finger prints are measured by means of a millimeter rule and a hand lens. Transfers by means of a platinum loop of pieces of agar from the centers of the clear zones to broth, controlled for possible subculture inhibition,⁴ demonstrate also bactericidal action if present. It may be said that in these experiments, when bacteriostatic

¹ Scott, W. W., Hill, Justina H., and Ellis, M. G. Action of Mercurochrome and Tincture of Iodine in Skin Disinfection. J. A. M. A. 92: 111 (Jan. 12) 1929.

action is demonstrated, the transfers are sterile that is, the test demonstrated both bacteriostatic and bactericidal action. It is necessary, however, to prove this by actual transfers for any drug so studied. The inclusion of solvent controls with every series is necessary. The water controls are even more important because of the occasional antibacterial action of normal skin.² *Staphylococcus aureus* was used in most of the tests, not only because of its significance on skin and in wounds but because of the strange inverse action of normal skin on bacterial spores,² upon which it exerts more action than on vegetative forms, making experiments with drugs and spores much less clearly defined than with such an organism as a staphylococcus.

It is obvious that, in a method involving the contact of a treated finger tip with an inoculated agar plate, the dimensions of any resulting zone of bacteriostasis will vary with the size of the finger print, the amount of drug on the skin, and the pressure of the finger, which should never be sufficient to crack the agar. The modification of Megrail and Hahn⁵ to control pressure by use of a torsion balance and a 5 Gm weight is of value. It seems to me that, although comparison of the total areas of inhibition gives the same general order of efficacy of the drugs tested, a better basis of comparison is the dimensions of the total zone of bacteriostasis minus that of the actual area of the finger print, as this difference at least partially offsets variations in the size of the prints. By doing a sufficient number of tests, with carefully impartial distribution of the fingers, this variation is further reduced and variations of pressure and of the amount of drug applied are equalized.

It is also obvious that tests of this type show that bacteriostatic action may be obtained with drugs after their application to skin and subsequent application to seeded plates, that is, the bacteriostatic test itself is not done while the drug is on the skin. We assume that if the finger tip coated with antiseptic transfers bacteriostatic action to a plate the antiseptic on the skin may also be exerting bacteriostatic action. Experiments in which the bacteriostatic action of the drug is tested while the drug remains both on the skin and in contact with the culture are described in series VII of this paper, but the technical difficulties of this long-contact method make it less feasible for large series than the finger-tip method.

SERIES I⁶—These tests represent the simplest form of the finger-print test, in which there was one application of drug and in which the contact of treated skin with the plates seeded with *Staphylococcus aureus* was made two minutes later, i. e., immediately after drying. Contact with the plate was for one minute only. In the series in which the 7 per cent tincture of iodine was removed with 70 per cent alcohol, it was necessary to apply the alcohol twice, the first time two minutes after the iodine, the second time one minute later, and the print was made two minutes after the second application. Five subjects were used, twenty tests apiece were made with the 7 per cent tincture of iodine and with the 2 per cent mercurchrome solutions, and ten apiece with the alcoholic solvents. Twenty tests with water only showed no action outside the finger print areas, but four of these controls showed very small amounts of bacteriostasis within the prints.

The rating of the solutions tested in this series in order of efficacy is given in table 1, as determined by the average dimensions of bacteriostasis obtained, minus the dimensions of the prints.

It is seen from this table that 2 per cent tincture of mercurchrome after its application to human skin is more bacteriostatic under the test conditions than tincture of iodine. The latter, not removed with alcohol, is more bacteriostatic under the same conditions than aqueous 2 per cent mercurchrome, but when the tincture of iodine is removed with alcohol, its bacteriostatic action is markedly less than that of either of the 2 per cent mercurchrome solutions.

SERIES II—Planimetric Readings—The method used was essentially the same as in series I, except that three applications of drug were made, and contact of treated skin with the inoculated plate was made five minutes after treatment. By measuring the areas of skin contact and of total bacteriostasis planimetrically and subtracting the former from the latter, it was found that the area for tincture of mercurchrome averaged 13.3 sq cm, for aqueous 2 per cent mercurchrome 8 sq cm, and for 3.5 per cent tincture of iodine 6.7 sq cm. It may be concluded from these experiments that both of the 2 per cent mercurchrome solutions are more bac-

TABLE 1—*Bacteriostatic Action of Drugs on Human Skin, Finger-Tip Method. One Application of Drug Followed by Contact with Staphylococcus Aureus*

Order	Drug	Average Dimensions of Bacteriostasis
1	Tincture of mercurchrome 2%	2.14 by 2.21 cm (Ave. 2.17 cm)
2	Tincture of iodine 7% not removed	1.71 by 1.70 cm (Ave. 1.70 cm)
3	Aqueous mercurchrome 2%	1.39 by 1.40 cm (Ave. 1.39 cm)
4	Tincture of iodine 7%, removed with alcohol	0.62 by 0.61 cm (Ave. 0.61 cm)
5	Alcohol 90%	0.46 by 0.51 cm (Ave. 0.48 cm)
6	Alcohol 55% water 35%, acetone 10%	0.03 by 0.1 cm (Ave. 0.09 cm)

teriostatic against *Staphylococcus aureus* on skin than is 3.5 per cent tincture of iodine, removed with alcohol.

SERIES III—These experiments are also similar to those of Series I except that three coats of the test drugs were applied five hours before the tests were made, and the fingers were kept loosely bandaged during the interim, but the hands were used. The test organism was *Staphylococcus aureus*, and, after removal of the bandages, contact with the plate was for five minutes. All of the twelve tests with aqueous 2 per cent mercurchrome and all of the eleven tests with tincture of 2 per cent mercurchrome showed both bacteriostatic and bactericidal action. No inhibition was obtained in the series of eleven alcohol, acetone, water solvent controls, and only one small area of bacteriostasis in the series of twenty-three water controls. These experiments have been confirmed by Megrail and Hahn⁵ (the first series of their report) and establish beyond any reasonable doubt the bacteriostatic and bactericidal action of both of the mercurchrome solutions on skin against *Staphylococcus aureus*.

SERIES IV—Dorsal Phalanges—These experiments, originated by Megrail and Hahn,⁵ were similar to the others except that the dorsal phalanges were used instead of the finger tips. Three applications of the drugs were made five hours before the test. The hands were actively used in the interim and washed as normally. The tests that my associates and I made showed bacteriostatic and bactericidal action in all of the ten

⁵ Megrail E. and Hahn R. C. Special Report to the Council on Pharmacy and Chemistry March 5, 1933 (unpublished).

⁶ Detailed protocols of the experiments described in this paper have been omitted as full publication requires too much space.

tests per drug with both 2 per cent mercurochrome solutions and with 3.5 per cent tincture of iodine. Our results differ from those of Megrail and Hahn (their IV-b). The number of variables is large and I believe that with exact definition of the number of washings and amount of use the differences would be eliminated.

SERIES V—*B. Subtilis* Spores—In this series five hours after treatment with three applications of the test drugs and after the superficial layer of drug had been at least partially removed by previous contact with *Staphylococcus aureus* plates for the experiments in Series III, second impressions were made on plates seeded with from four to seven day *B. subtilis* spores. Bacteriostatic and bactericidal action was observed in all of the eight tests with 2 per cent aqueous mercurochrome, in all of the five tests with 2 per cent tincture of mercurochrome, in none of the five tests with the alcohol, acetone, water solvent, and in only two of the thirteen water controls. Thus bacteriostatic amounts of either of the 2 per cent mercurochrome solutions may remain on the skin after removal of the most superficial layer of drug by previous contact.

SERIES VI—*Anthrax* Spores—In a series with ninety day anthrax spores, contacts were made either three minutes or twelve hours after three applications

TABLE 2—Summary of All Bacteriostatic Tests with Mercurochrome on Skin, Without Removal of Mercurochrome by Scrubbing

Drug	Total Number of Tests	Number Showing Bacteriostatic and Bactericidal Action	Number Not Showing Bacteriostatic and Bactericidal Action
Mercurochrome 2%, aqueous	68	68	0
Mercurochrome 2% tincture	63	63	0
Alcohol acetone water control	37	7 (18.9%)	30
Water control	68	11 (16.2%)	57

of the test drug. In three tests each with the two 2 per cent mercurochrome solutions larger zones of bacteriostatic action were obtained than with the three tests with the tincture solvent and with the four water controls. It was an extraordinary fact that all four of the normal skin controls showed both bacteriostatic and bactericidal action against these virulent spores. The drug tests therefore indicated an increased action but could not be regarded as bactericidal tests. It was impossible to do a long series of these tests on a number of individuals, but it may certainly be concluded that the application of either of the two mercurochrome solutions markedly increased the bacteriostatic action of the normal skin tested against anthrax spores.

SERIES VII—In an effort to keep treated skin and cultures in contact during the incubation period, a departure was made from the finger print method. Agar cultures of *Staphylococcus aureus* were prepared in sterile watch glasses. Either three minutes or five hours after three applications of the drugs to the skin, the cultures were strapped on the thigh for an eighteen hour period. When the cultures were removed after eighteen hours, all of the series of eight treated with aqueous 2 per cent mercurochrome and all of eight treated with tincture of mercurochrome were sterile, as shown by subcultures, the eight in the series of the solvent control for the tincture and the eight water controls showed massive growths of the test organisms. This method, as stated, is not satisfactory for a long

series, because of the possibility of infection in the control areas, and as suggested by von Oettingen⁶ because of possible action of unevaporated sweat on diffusion of the drug, in the areas excluded from air by application of the cultures. It may, however, be concluded from these experiments that both bacteriostatic and bactericidal action was obtained under the test conditions with both of the mercurochrome solutions.

Summary of Tests on Skin, Unscrubbed—All of these tests on human skin with aqueous 2 per cent or 2 per cent tincture of mercurochrome and with the solvent controls, in which the drug was applied to the skin two minutes, five minutes, five hours or twelve hours before contact with the bacteria, *Staphylococcus aureus*, or spores of *B. subtilis* or of *B. anthracis*, may be summarized as in table 2.

This shows clearly that in all the tests both the aqueous solution and the tincture of mercurochrome were bacteriostatic on human skin. With the exception of the few cases in which the solvents showed some action, this was also bactericidal action.

Scrubbing Experiments—In addition, four series were done to determine what, if any, action might remain after the use of the hands and removal of the drugs by various types of scrubbing. These experiments are of secondary importance, in that the clinical use of tincture of mercurochrome in preoperative skin disinfection does not involve the removal of the drug as in the case of iodine. They may, however, have some bearing on the maintenance of bacteriostatic action on skin during operation or around wounds treated with the aqueous solution.

SERIES VIII—Scrubbing Experiments—A The finger tips were given three coats of the drugs and left unbandaged, for five hours after treatment, while the hands were in use. They were then scrubbed for three minutes in cold running water without soap and prints were made on *Staphylococcus aureus* plates. With both of the mercurochrome solutions, seven of a total of ten tests still gave bactericidal and bacteriostatic action, while none of the ten alcohol, acetone, water controls or of the twenty water controls showed any action.

SERIES IX—Scrubbing Experiments—B (Megrail and Hahn, series II) In these experiments the fingers were given three applications of drug, not bandaged, used for five hours, washed during this period, then scrubbed for three minutes in cold running water with a soft brush and soap, dried on a paper towel and then printed on *Staphylococcus aureus* plates. This method originated with Megrail and Hahn⁶. Our results do not correspond with theirs. We found bacteriostatic action in seven out of ten tests with aqueous 2 per cent mercurochrome, in all of our five tests with tincture of mercurochrome, in five tests with 1:1,000 merthiolate, and in four out of five with 3.5 per cent tincture of iodine. As in series IV, in which our observations and those of Megrail and Hahn did not check, the number of variables is very large and I believe that a further refinement of methods would eliminate the discrepancy.

SERIES X—Scrubbing Experiments—C (Megrail and Hahn, series III) In these experiments after three coats of drug, the hands were used for five hours and then scrubbed for three minutes in cold running water without soap. These experiments originated with Megrail and Hahn, with whom we are in agreement.

We observed bacteriostatic action in three out of the four tests with aqueous 2 per cent mercurochrome, in all of the four tests with tincture of 2 per cent mercurochrome, in all of the four tests with 1,000 merthiolate, in three out of four tests with 3.5 per cent tincture of iodine, and none with the solvents. Parallel tests done with only one application of the mercurochrome solutions gave the same results as three applications.

SERIES XI—Scrubbing Experiments—D (Megrail and Hahn, IV-a) In these experiments the dorsal phalanges were given three applications of drug, used for five hours, and then scrubbed for three minutes with soap. Our results showed bacteriostatic action in eight out of nine tests with aqueous mercurochrome, in ten out of eleven with tincture of mercurochrome, and in nine out of ten with 3.5 per cent tincture of iodine. The discrepancies between our results and those of Megrail and Hahn in this type of test, open to extreme variation, are explicable on the same grounds as those in series IV and series IX.

PART II WOUND EXPERIMENTS

Even less approach has been made to possible standard methods of studying the action of antiseptics in wounds than on skin and the development of such methods is urgently needed. The fact, established by Carrel and Dehelly⁷ and by Sir Almroth Wright⁸ that no one application of any drug will sterilize a heavily infected wound seems to have been forgotten. Exact information in regard to the behavior of drugs in wounds is appallingly lacking. The recent paper by Simmons⁹ represents a step in the right direction, although I believe that the time periods of his tests were too short. We have confirmed his short time experiments but, by extending the time to twenty-four hours, have shown that his conclusion that wounds were sterilized by tincture of iodine cannot be maintained. Certainly, in the use of any drug for first aid or in other types of wounds there is need for emphasis of this fundamental limitation of any drug used for these purposes, at least until sterilization shall be proved beyond question.

Two methods are given here, one for determination of the effect of one application of a drug, as studied in a twenty-four period, the other a method of studying the rate of healing of local abscesses, treated repeatedly until healed. The methods are suggested as a basis for the elaboration of standards by which the action of drugs may be determined and comparative studies made.

A Short Time Tests—Method After a number of preliminary tests, the final method employed was as follows. Large guinea-pigs were shaved over the abdomen and thorax. From four to eight carefully separated 1 cm incisions through the skin were made. By means of blunt dissection, subcutaneous pockets about 1 cm deep were made round the edges of each incision. These were inoculated with *Staphylococcus aureus*, by means of one cotton swab per wound, the swab being saturated with an eighteen hour broth culture of the cocci. Five minutes later, by means of swabs moistened in sterile broth, two for every incision,

smears were made for preliminary wound counts, and cultures were made on agar plates and in broth, as an inoculation control and as a basis for comparison for later cultures. Treatment was then given by flooding the wound with the test drug on a saturated swab, which could be rotated in the wound until the excess fluid appeared at the opening. All but one of the wounds in a given animal were treated with a given drug, and one wound per animal was treated with water only and separately dressed. The skin around the wounds was also covered with the test drug. Sterile dressings were then applied, held firmly in place with adhesive tape and with an outside belt of sterile unbleached muslin. It was necessary to bind the animals' hind feet to keep them from kicking. Possible contamination with excreta was controlled by the application of collodion to the lower edge of the dressings. The sources of error in this technic when perfected were few and the same for all the drugs. Twenty-four hours later the dressings were removed and smears and cultures were taken, the greatest care being taken to use separate sterile instruments for each wound to lift up the edge of the incision so

TABLE 3—Summary of Twenty-Four Hour Counts, in Wounds Heavily Inoculated with *Staphylococcus Aureus* and Given One Application of the Test Drug

Treatment	Average Number of Cocci per Field	Percentage of Cocci Phagocytized	Number of Leukocytes per Field
1 Mercurochrome 2%, aqueous	6.7	18.4	1.25
2 Mercurochrome 2% tincture	18.2	1.9	0.7
3 Merthiolate, tincture	33.2	7.5	0.83
4 Alcohol, 65%, water 35% and acetone 10%	41.9	7.5	2.0
5 Water only (control)	75	17.6	6.5
6 Tincture of metaphen 1:200	91.3	2.85	0.3
7 Acriflavine, 1:1,000, in saline solution	99.8	1.23	0.4
8 Hexylresorcinol	100.9	8.0	1.29
9 Merthiolate aqueous	112.2	8.5	1.65
10 Alcohol 90%	114.7	8.7	0.99
11 Tincture of iodine 7%	137.0	0.9	0.25

that only the inner part of the wound was touched by the swabs.

The results at the end of twenty-four hours are summarized in table 3. Counts before treatment were somewhat variable, because of the presence of blood in some cases, but they ranged from 0.5 to 5 cocci per field, with an occasional higher count, the maximum, obtained once, being thirty. Cultures from all wounds, both before and after treatment, have been positive.

It is possible by examination of smears as well as by cultures to study three points: (1) the number of cocci per field, (2) the percentage of them that have been phagocytized, and (3) the number of leukocytes per field. These may be briefly discussed.

Twenty-four hours after treatment, the water treated controls averaged 75 cocci per field, 17.6 per cent of which were phagocytized. The number of leukocytes per field was 6.5. These figures may be taken as a basis of comparison. It is seen from table 3 that the lowest count was with the aqueous 2 per cent mercurochrome solution, which kept the bacterial count down to an average of 6.7 cocci per field without reducing the percentage of organisms phagocytized, which was 18.4 per cent. This was the only solution that did not decrease this percentage. The number of white cells per field was reduced by every drug used. The tinc-

⁷ Carrel, Alexis and Dehelly, G. Treatment of Infected Wounds New York, Paul B. Hoeber, Inc., 1917.

⁹ Simmons, J. S. The Comparative Bactericidal Action of Mercurochrome and Iodine Solutions Used as Local Tissue Disinfectants. Surg. Gynec. & Obst., 56: 55 (Jan.) 1933.

ture of 2 per cent mercurochrome kept the count down to 182 cocci per field but caused a reduction of the percentage phagocytized to 19 and of the number of leukocytes per field to 07. The solvent control for the tincture of mercurochrome kept the bacterial count at 419 per field, reduced the percentage phagocytized only to 74, and the number of leukocytes per field to 2. As compared with these observations, it is seen that the number of cocci per field after treatment with 7 per cent tincture of iodine was 137, markedly more than the number in the water treated control, the percentage of cocci phagocytized was only 09, and the number of leukocytes per field was reduced to the low average of 0.25. The 90 per cent alcohol solvent control for the tincture of iodine also gave a count above the water control, i. e., 1147 cocci per field, the percentage phagocytized was reduced to 37, the number of leukocytes per field to 099. Of the other drugs tested only the tincture of merthiolate gave a bacterial count under the water treated controls. This solution kept the count down to 333 cocci per field, but reduced the percentage of cocci phagocytized to 75 and the number of leukocytes per field to 086.

It is evident from these tests that under the conditions of the experiments the aqueous 2 per cent solution of mercurochrome was superior to the other drugs studied. This is an interesting observation because tincture of iodine has a much more rapid *in vitro* bactericidal action than aqueous 2 per cent mercurochrome, and merthiolate has a much higher *in vitro* bacteriostatic action. The slow bactericidal action of mercurials has been demonstrated repeatedly¹⁰ but should be considered in relation to their bacteriostatic action. Considering these observations in relation to the fact that in the aqueous mercurochrome series the percentage of cocci phagocytized remains at least as high as in the water control series while the percentage of cocci phagocytized is very low in the series treated with tincture of iodine or with tincture of metaphen, it seems proved that the powerful immediate antibacterial action of iodine and of metaphen is offset under these conditions by their injurious effect on the tissues.

In comparing aqueous mercurochrome and tincture of mercurochrome in these wounds, the advantage clearly belongs to the aqueous solution, which gives a markedly lower bacterial count, a much higher percentage of phagocytosis and a higher leukocyte count. Leukocytosis and phagocytosis have long been recognized as the most important agents with which our bodies fight infection. The fact that the moderate antiseptic mercurochrome in aqueous solution does not interfere with phagocytosis explains in part its efficacy in wounds.

B Long Time Tests—In 1928 a series of wound experiments in guinea-pigs was reported.¹¹ Additional experiments have since been done by the same method, including a series of saline treated controls, in order that conclusions might be made in regard to local action. The method, fully described in the earlier paper, consisted of making a 1 cm incision in the abdominal skin of a guinea-pig blunt dissection subcutaneously round

the edge of the incision, and after the insertion of a few crumbs of aleuronat paste, inoculation of the wound with *Staphylococcus aureus*. Within forty-eight hours, abscesses are formed with high initial bacterial counts and many leukocytes. These lesions are regularly obtained and are suitable for the study of relative rates of healing, as they may be followed by means of daily wound counts until healed and repeated applications of a drug may be made.

While the rate of healing of the untreated controls was nineteen days, the local application of either 1 or 2 per cent aqueous mercurochrome reduced the healing time to eleven days. Treatment with saline solution, on the other hand, increased the healing time to twenty-six days.

SUMMARY AND CONCLUSIONS

1 There is urgent need for standard methods of studying the *in vivo* action of antiseptics for special uses. In this paper methods are suggested which, on further refinement, might serve as bases for such standards.

2 In regard to the action of antiseptics applied to the skin, it is shown that

(a) Under conditions of practical use no antiseptic studied can invariably sterilize heavily infected skin.

(b) Aqueous solutions of antiseptics are not as a rule suitable for preoperative skin sterilization.

(c) Both the 2 per cent tincture and 2 per cent aqueous mercurochrome solutions are bactericidal and bacteriostatic on human skin. The 2 per cent tincture of mercurochrome is superior to the aqueous solution on the skin, as has been shown previously. Only the tincture has been advocated for preoperative skin sterilization.

(d) If comparisons are to be made between the bacteriostatic actions of preparations of iodine and mercurochrome on the skin, the order of efficacy, according to the results of our experiments, is as follows: first, the 2 per cent tincture of mercurochrome, second the 7 per cent tincture of iodine, not removed with alcohol, third, the 2 per cent aqueous solution of mercurochrome, fourth, the 7 per cent tincture of iodine, removed with alcohol.

3 In regard to the use of antiseptics in wounds, it is shown that

(a) It is improbable that a single application of any known antiseptic will sterilize a heavily infected wound.

(b) There is evidence that while both the tincture and aqueous solutions of mercurochrome are bacteriostatic in heavily infected wounds, the aqueous solution, under the conditions of the tests, is superior to the tincture of mercurochrome and to the other antiseptics tested in that it keeps the bacterial count lower and does not interfere with phagocytosis.

The Presiding Follicle—Just after a menstrual period a number of follicles or egg-sacs in the ovaries begin to grow but, for some curious reason, one of these outstrips its fellows and is destined to become the presiding follicle so to speak, of that particular monthly cycle. It reaches full bloom, i. e. full maturity about half-way before the next period, though sometimes considerably earlier sometimes considerably later. As it grows it produces increasing amounts of its hormone, which is often spoken of as the female sex hormone. This particular hormone has the effect, once it gets into the blood stream of producing a steadily increasing growth of the lining mucous membrane (endometrium) of the uterus and of gradually increasing the amount of blood in the latter.—Novak, Emil. *The Woman Asks the Doctor*, Baltimore: Williams and Wilkins Company, 1935.

TREATMENT OF TRICHOMONAS VAGINITIS WITH CONCENTRATED SALT SOLUTION

LAZAR ROSENTHAL, MD
LEO S SCHWARTZ, M.D.
AND
JOSEPH KALDOR, MD
BROOKLYN

At present, various chemical agents are being applied in order to destroy *Trichomonas vaginalis*. However, chemotherapy is frequently unsatisfactory for the following reasons: 1 In order to be effective, many chemicals must be used in concentrations that may be harmful to the vaginal mucosa, especially during prolonged treatment. 2 There is always a possibility that in the course of treatment a strain of the parasite may develop that is resistant to the chemotherapeutic agent. 3 Most of the chemotherapeutic methods are relatively complicated and cannot be applied by the patient at her home.

Taking into consideration the fact that protozoa in general are sensitive to variations in osmotic pressure of the surrounding medium, it occurred to us that the vaginal protozoon may also be affected by such variations. We therefore decided to study the action of hypertonic salt solutions on *Trichomonas vaginalis*.

The fact that *Trichomonas vaginalis* is an extracellular parasite living free in the vaginal secretion made it possible to conduct the experiments in vitro. We collected the vaginal discharge through a speculum with a cotton swab and transferred it into a test tube containing from 2 to 3 cc of physiologic solution of sodium chloride. The fluid, after shaking, was examined in a wet preparation under the high dry power of the microscope. For our investigations, only material which contained numerous motile parasites was used.

A drop of this trichomonas suspension was mixed on a slide with a drop of hypertonic solution of sodium chloride. The mixture was covered with a cover slip and immediately examined under the high dry power of the microscope. We performed this experiment with four dilutions of sodium chloride: 3, 6, 12 and 25 per cent respectively. We are recording only those changes in the trichomonas which took place immediately after the addition of the salt solutions. The 3 and 6 per cent salt solution apparently did not affect the parasites. They remained as actively motile as in the control preparation with physiologic solution of sodium chloride. Entirely different pictures were obtained when salt solutions of 12 and 25 per cent were used. The motility of the parasites stopped instantaneously and their shape underwent a radical change. The parasites became shrunken and crenated. To all appearances they were dead.

But here we had to consider the following facts: Investigations of Schewiakoff¹ with sea infusoria had brought to light the fact that these protozoa when transferred from their habitual surroundings to a more concentrated salt solution rapidly became inactive and changed their outward appearance. When these apparently dead protozoa were returned to the sea water, they regained their motility and became active again. This temporary cessation of life activities under the

influence of concentrated salt solutions is known under the name of "salt anabiosis." With reference to *Trichomonas vaginalis*, we could demonstrate that the transfer of the parasites immediately after their inactivation from a 12 per cent solution into a physiologic solution restored their normal shape and motility. The 25 per cent salt solution, however, made the phenomenon of inactivation permanent and irreversible. The parasites could not be returned to life when transferred to a physiologic salt solution.

On the basis of these experiments we began to apply salt in the treatment of patients suffering with trichomonas vaginitis. At first we used vaginal insufflation with finely powdered salt and then we tried to pack the vagina with gauze saturated in a 25 per cent salt solution. This packing was left in the vagina for twenty-four hours. A few patients having reported discomfort and burning pain in the vagina, we discontinued this mode of treatment and adopted the vaginal douching with a 25 per cent solution of salt.

The patient herself at home can easily prepare an approximately 25 per cent solution by dissolving 1 glassful of salt in 4 glassfuls of hot water. In order to secure an abundant vaginal flush, this amount of salt and water can be doubled. The solution is used at body temperature. The douching is well tolerated by the vaginal mucosa and does not cause any irritation or discomfort.

The combined number of our clinic and private cases was fifty-six. The diagnosis in all cases was confirmed by microscopic examinations. In all cases the characteristic symptoms of trichomonas vaginitis were present. The patients complained of itching and burning about the vulva. The vaginal discharge was more or less profuse, sticky, purulent and foamy, with a peculiar foul odor. In most cases the vaginal mucous membrane, especially in the fornices and on the cervix, presented pinpoint to pinhead sized granulations.

In nearly all cases the relief was prompt after one or two daily douches. The itch disappeared, the discharge became scanty, thin in character and odorless, or even disappeared entirely, and the vaginal mucosa assumed a normal appearance.

In thirty cases, no more live trichomonas organisms could be found after two or three douches. Twenty-four cases showed complete absence of live parasites after one week of daily douches and two cases required two weeks of daily douches to bring about the disappearance of the parasites.

It is a known fact that, with every method of treatment, the trichomonas vaginitis has a tendency to recur after menstruation.

In our series, during an observation period of eight months the recurrence of *Trichomonas* did not take place in twenty cases after one month of treatment, in twelve cases after two months of treatment, and in sixteen cases after three months of treatment.

Therefore by this method forty-eight patients, or 85.7 per cent, could be considered clinically and parasitologically cured after three months of treatment. The rest of the series (eight patients) performed the treatment very irregularly and their parasitologic examinations accordingly varied at different times. These cases were not considered as cured.

According to Davis² it is doubtful whether any type of home treatment will result in complete destruction of *Trichomonas vaginalis* or in a clinical cure that will

From the Department of Obstetrics and Gynecology and the Department of Laboratories, Israel Zion Hospital.

² Davis C. H. Lenkerhca in Curtis H. H. Obstetrics and Gynecology Philadelphia W. B. Saunders Company 3: 439, 1933.

persist for more than a few weeks. Our method, which is easily executed by the patient at home, gives a definite and prompt relief and prevents recurrence in a considerable number of cases.

CONCLUSIONS

1 Vaginal douching with 25 per cent salt solution is proposed for the treatment of trichomonas vaginitis.

2 The principle of the treatment is based on the osmotic effect of concentrated salt solution on trichomonas vaginalis.

3 The method is nonirritating, simple and inexpensive and can easily be carried out by the patient at home.

4 The method gives prompt relief from the itching and irritating vaginal discharge and prevents in most cases the recurrence of trichomonas vaginitis.

PREPUTIAL CALCULUS, A CLINICAL RARITY

REPORT OF A CASE

NORMAN R. INGRAHAM, JR., M.D.
PHILADELPHIA

History—A Negro, aged 30, admitted to the Genito-Urinary Service of the Philadelphia General Hospital, Dec 4, 1933, complained chiefly of acute urinary retention. Since birth he had never been able to retract the foreskin of the penis. Urine was expelled in a fine stream through a narrow opening in the prepuce. At each attempt at micturition, the urine flow being retarded not at the meatus but at the preputial orifice, there was a ballooning of the foreskin to form a sac, which had to be emptied by manual compression. For some months prior to admission, however, he had been unable to empty this preputial sac completely because of the presence of some hard substance, which he could easily feel in this structure with his fingers. This had increased rather rapidly in size until the sac had become swollen and hard, as though filled with stone. With the appearance of the foreign bodies, micturition which up to then had been comparatively easy had become increasingly difficult. On the day of admission he found himself, for the first time, unable to void, and he had not passed urine for twelve hours prior to coming to the hospital.

The remainder of his genito-urinary history was irrelevant. He stated that sexual relations were normal up to the appearance of the preputial stone, semen passing readily through the preputial orifice, but this had been impossible for the past few months.

Physical Examination—He was well developed and well nourished, apparently in good health save for the difficulty that brought him to the hospital, and he was normal physically except for the genito-urinary condition. The chest and heart were normal, the blood pressure was 125 systolic, 65 diastolic. The bladder extended half way to the umbilicus, the lower part of the abdomen was tender. The head of the penis was surmounted by an ovoid structure 4.5 cm in diameter, at the tip of which was a small opening 2 mm in diameter for the passage of urine. Palpation revealed a hard irregular mass beneath the foreskin with definite crepitation, as though stones were present. There was absolute urinary retention.

The body of the penis was large but otherwise normal. The left testicle was swollen and the epididymis was enlarged and tender. Rectally the prostate was a little large and boggy but not otherwise remarkable.

Treatment—On coming to the ward, he was placed immediately on the examining table and unsuccessful attempts were made to pass a flexible bougie and a metal catheter. The grating of the latter instrument on the foreign body left little doubt that there were stones, either in the anterior urethra, on the assumption that the foreskin was adherent to the glans, or in the preputial sac. An operative procedure was in order, an incision was carefully made over the dorsum of the mass and

a pocket of stones was revealed between the prepuce and the glans. One of the larger calculi pushed against the meatus accounted for the retention. Circumcision was performed. He voided 60 ounces (1,800 cc.) of urine in the next twelve hours. The urethra was considerably dilated and the glans slightly atrophic but otherwise normal.

Course in Hospital and Studies—Because of the infection of the epididymis and testicle, resulting undoubtedly from a retrograde passage of bacteria from the posterior urethra through the vas attending the acute retention, he had a temperature elevation up to from 101 to 103 F daily until December 25. An abscess in the left scrotal sac was incised and drained December 13. An intravenous pyelogram showed no evidence of stone in the kidneys or bladder and good kidney function. There was some ureterectasis of the proximal end of the right ureter. Cystoscopy, performed Jan 23, 1934, revealed a normal bladder with no stones. He was discharged the same day, completely cured.

The urine, Dec 5, 1933, was yellow, acid, with a specific gravity of 1.021, a faint trace of albumin, no sugar, leukocytes 1+, and an occasional epithelial cell.

Examination of the blood showed, December 15, red blood cells, 3,300,000, hemoglobin 70 per cent, white blood cells, 8,400. December 26, red blood cells, 3,820,000, hemoglobin, 70 per cent, white blood cells, 8,300. The Kahn test was 4+, the cholesterol test, 4+, and the Noguchi reaction, 2+. Sugar was 89 mg per hundred cubic centimeters, urea nitrogen, 15 mg.

Description of Stones—The stones, shown in the accompanying illustration, numbered 1,072 and weighed 76 Gm. They were worn smooth from constantly rubbing on one another and many were faceted. The dimensions of the seven largest are given in table 1. Their analysis, according to Dr Reinhold, was as follows: The stones consisted of a gray smooth core surrounded by layers of white chalky material. The outer lamina was chiefly calcium (and magnesium) carbonates plus a small admixture of protein-like material and traces of urate. The inner core and surrounding gray lamina were largely calcium carbonate but contained considerable protein material as well and some urate. There was no cholesterol, cystine or ammonium salts. No crystals were found.

THE AMERICAN LITERATURE

The extreme unusualness of this clinical condition, as judged by the paucity of the literature on the subject, particularly in America, makes some comment on it seem necessary. In this country, Gross¹ in 1866 had evidently never seen a case of preputial calculus, but he mentioned the fact that he had in his possession stones obtained from the preputial sac of a Chinese by Dr John G. Kerr² of Canton, China. Keating³ mentioned the condition of calcified smegma occurring in children without complete phimosis (set forth previously by Demarquay⁴ and recounted more recently by Heymann⁵ in adults) and described a case of preputial calculus associated with bladder stone. Nelson⁶ in 1872 reported the case of a Chinese of Sacramento, Calif., aged 35, who had thirty-eight calculi varying in size from number 6 shot to buckshot, in a preputial sac phimosed since childhood. Buchelmann⁷ in 1881 told of a case of this condition occurring in a Mexican, aged 60, in which there were two stones, 3.5 cm and 5.3 cm in diameter. Jenkins⁸ in 1887 found two calculi,

2 cm by 1 cm, in a 3 year old Negro boy in Henderson, Ky. More recently, Williamson⁹ performed a circumcision on a 15 year old Negro boy in Norfolk, Va., and found five uric acid calculi, in the preputial sac, the largest 7 mm in length.

THE FOREIGN LITERATURE

While the occurrence of preputial stone probably dates from the origin of man, the first recorded case in the readily accessible literature is that of Robert Clarke,¹⁰ preserved in the Philosophical Transactions

TABLE 1—Dimensions of Seven Largest Stones

Stone	Size in Centimeters
1	2.7 by 2.0 by 1.5
2	2.4 by 1.9 by 1.0
3	2.2 by 2.0 by 1.7
4	2.0 by 1.7 by 1.2
5	1.9 by 1.6 by 1.0
6	1.7 by 1.5 by 0.9
7	1.5 by 1.4 by 0.8

of the Royal Society of London in 1749. (A case seen in Paris in 1722 by Petit¹¹ was not reported until 1753.) Clarke's case is of especial interest since it describes briefly and dramatically the course which this condition, untreated, takes.

A man, aged 23, "from infancy labored under difficulty of making water. He was in greatest agony from every motion, but was relieved by putting a great pin, the head foremost, an inch at least between the prepuce and the stone, when sometimes mucous, sometimes a gritty matter would first ooze out and then came urine with some violence. During this time (from the age of 3 to 23 years) the end of the penis was observed to grow in the form of and as large as a hen's egg, occasioned as may be imagined by the concretion of the stone between the glans and the prepuce. At last there was a total suppression of urine for 48 hrs at least attended by the appearance of a sore on the side of the penis out of which the stony concretion dropped."

Demarquay,¹² Lewin¹³ and Englisch¹⁴ have more or less completely reviewed the literature up to 1903. They found some fifty-two cases occurring at almost any age (table 2).

No age given	17

The stone occurs usually singly or a few in number, only four cases are mentioned in which there were more than 100 stones (greatest number 400, by Winshaw of Fyzabad, India¹⁵). Some very large stones have been described. Thus Sabatier describes a preputial stone 6.9 cm in diameter and 15.3 cm in circumfer-

ence, weighing 141 Gm.¹⁶ Levavasseur¹⁷ found a stone weighing 210 Gm in a Frenchman of Carcassonne, aged 44, with congenital phimosis. Mathew¹⁸ obtained one from a Brahmin of Mazufferpore, India, 17.8 cm in circumference and weighing 222 Gm, while Vanzetti¹⁸ found a calculus measuring 8 cm by 6 cm and weighing 224 Gm, in a Ukrainian peasant.

From 1903 to date some thirty-seven cases are reported, most of them from outlying districts and in no sense remarkable. McCracken¹⁹ describes a case seen by him in Shanghai, China, in which 395 small stones were obtained from the preputial sac of a 35 year old man. Ramaroni²⁰ obtained forty-five small stones weighing 272 Gm from a 33 month old child in Paris. Griewank,²¹ in 1914, described the most remarkable case yet on record.

A 25 year old native of Upper Senegal and Niger was improperly circumcised at the age of 15 years, much redundant tissue being left which, in the ensuing ten years, closed down until only a small opening was left. The head of the penis grew to the size of the head of a fetus at term and spherical. The wall of the prepuce, thickened by inflammatory tissue, was 3 cm wide. The sac was filled with calcium ammonium phosphate stones to the number of from 1,800 to 2,000 and weighing 540 Gm.

Calculi obtained from the preputial sac of a Negro aged 30, with congenital phimosis.

SUMMARY OF IMPORTANT FACTS

Preputial stone occurs in those cases of phimosis, usually congenital in origin, in which the orifice for the passage of urine becomes so small that stagnation occurs in the preputial sac, distended by pressure of urine from the bladder. The anterior urethra becomes dilated,⁸ and the bladder hypertrophies and enlarges.¹⁰ Hydro-ureter may develop if the condition continues over a long period of time. Infection of the bladder, posterior urethra, epididymis and testicle may occur and urinary extravasation may result.¹⁷ Particularly in the presence of infection, the debris from which forms a nucleus, stagnation of urine is apt to result in the deposit of urinary salts to form calculi either in the kidneys,²² bladder or preputial sac. Those formed high up in the urinary tract are caught by the phimosed prepuce if

they are carried downward by the urine flow, and the result is the same as though they were formed in the latter situation. The stones consist of organic matter impregnated with calcium or magnesium phosphate or urate, occasionally of ammonium salts or uric acid.²³ They increase more or less rapidly in size as successive layers are deposited. Venereal disease, by narrowing the outlet for urine flow and increasing the tendency to fibrosis, makes the formation of preputial stone more likely.²⁴ If the case goes untreated, urinary obstruction of severe degree will sooner or later develop, which without intervention, may give rise to the formation of a fistula.²⁵ Chronic irritation has caused the development of cancer of the glans in at least one instance,²³¹ and pressure atrophy of the glans is common.²⁶

The diagnosis rests on the realization of the existence of such a condition, and the treatment without exception, is circumcision.

RAPIDLY DEVELOPING CATARACT AFTER DINITROPHENOL

W W BOARDMAN, M D
SAN FRANCISCO

Dinitrophenol has been demonstrated to be a marked metabolic stimulant and as such has been recommended as an aid in the treatment of obesity. Extensive animal experimentation and a carefully controlled series of clinical cases convinced Dr M L Tainter and his co-workers that dinitrophenol in proper dosage and properly controlled produced no deleterious effect on the human organism.

A few cases have appeared in the literature in which death occurred after the ingestion of dinitrophenol, but in these cases there had been excessive dosage or the drug had been continued after the appearance of some complicating condition. At the present time, dinitrophenol is quite generally accepted as an adjunct in the treatment of obesity, although among the more conservative it is used cautiously and with a certain degree of fear.

I myself have used it in several cases and with satisfactory results. However, in the last two weeks I have seen two cases of rapidly developing cataract in relatively young women and have had reports of four similar cases.

REPORT OF CASES

CASE 1—Mrs L, aged 50, was given dinitrophenol off and on from October 1933 to May 1935, with a loss of weight from 237½ pounds (107.7 Kg) to 161 pounds (73 Kg). May 2 she complained of dimness of vision and was referred to Dr W D Horner, who reported incipient cataractous changes in both eyes. He stated that these changes suggested a toxic or metabolic disturbance rather than the usual senile cataract. Within a week the changes progressed so rapidly that only light and dark could be distinguished.

Huyborchts T. *Presse med* 55 299 1903. 25 McCracken, Tucker and Snell. Clarke. 26 Demarquay. Nelson.

CASE 2—Mrs A, aged 36, was given dinitrophenol in doses of from 100 to 500 mg daily from January to August 1934, with a loss of weight from 217½ pounds (98.6 Kg) to 165 pounds (74.8 Kg). From August 1934 to March 1935 the drug was discontinued. By this time she had gained back to 198½ pounds (90 Kg). Dinitrophenol was again given until Mar 1935 when an eye examination by Dr Horner disclosed incipient cataracts. Vision failed rapidly, so that within a month there was almost complete loss of vision in the right eye.

CASE 3—A woman, aged 39, whose case was reported by Dr A B Stockton, had been given dinitrophenol interruptedly over a period of eight or nine months with satisfactory weight reduction. In November 1934 she reported that her vision was getting dim and within thirty days the condition had progressed to almost complete blindness and with fully developed cataracts.

CASE 4—A woman, aged about 40, whose case was reported by Dr J R. Sharpsteen of Oakland, had been taking dinitrophenol without a physician's supervision for several months. She also has shown rapidly developing cataracts.

CASES 5 and 6—Two other cases, reported by Oakland physicians, have occurred of rapidly developing cataracts in women who have been taking dinitrophenol.

COMMENT

As the occurrence of cataract at this age is extremely rare and the only common factor in these cases has been the use of dinitrophenol it would certainly seem that until the question of the relationship between the dinitrophenol and the rapidly developing cataracts in young women is settled, the administration of the drug is definitely contraindicated.

490 Post Street.

CATARACTS FOLLOWING THE USE OF DINITROPHENOL

PRELIMINARY REPORT OF THREE CASES

WARREN D HORNER, M D
RICHARD BARR JONES, M D
AND
W W BOARDMAN, M D
SAN FRANCISCO

CASE 1—April 25 1935, a woman aged 50, reported for eye examination having been referred by Dr Richard Jones. She complained of blurred vision and was sure that she needed new glasses although she had received some from an optometrist only six months before.

Examination showed vision of 01 in each eye corrected to 03 with her glasses. Externally the eyes were not remarkable. Stereoscopic vision, perimetric fields, color sense and muscle balance were normal. Fundus examination showed partial cataracts in each eye. The eye backgrounds were indistinct but were grossly normal. Under dilation the slit lamp showed the cornea, iris and anterior chamber normal. The anterior lens capsule in each eye showed a peculiarly spotty, dry, lusterless appearance resembling the body of a fish out of water or a cornea that lacked tears. Just beneath the capsule fine light gray cloudy opacities were apparent.

There were a few irregular, pearl gray opacities lying deeper in the cortex. The posterior lens showed a remarkable yellowish green reflex and a scumlike metallic sheen not unlike the surface of dull brass that had been irregularly scratched. These lay in the cortex just beneath the posterior capsule and were not to be confused with the normal shagreen.

Refraction showed R. E. +3.00 sph \ominus +0.50 cyl axis 180° V 06 and J 62 blurred with +1.75 add. L. E. +3.00 sph \ominus 0.25 cyl axis 180° V 08 and J 50. The old glasses were approximately 50 per cent weaker in sphere. The appearance of the lens suggested either a toxic or a metabolic disturbance. Questioning revealed that the patient had been taking dinitrophenol under strict medical supervision and had lost 75 pounds (34 Kg). Communication with her physician revealed an absence of glycosuria, nephritis or any other physical condition that might bear on the cataracts.

For lack of something more efficacious, a solution of 3 per cent boric acid in glycerin was ordered for instillation in each eye twice daily.

One week later, May 2, vision, previously 06 and 08 with correction, was reduced to less than 01. The patient preferred her old glasses, which contained 50 per cent less sphere, a marked change in refraction.

May 6, vision in the right eye was less than 01, not improved, but she preferred a -0.50 to -1.00 sphere. The left eye vision was 02, with $+1.75$ sphere, V 06. With $+1.75$ add, she read J 150 partly.

May 8, V R E. = chart only unimproved V L E 06. She would accept no plus but preferred plano V 06. Intra-ocular tension measured R E 29 and 23 (Schiotz) at two day intervals, L E 22 and 31.

Under the slit lamp the lenses showed a dry, pebbly anterior capsule and a remarkable increase of bright pearly deposits in the anterior and central portions. These showed segmentation with dark spaces in between. The posterior layers could no longer be seen. Opacification was increasing rapidly. May 13 vision R E was reduced to light of chart unimproved V L E 01 partly, with minus sphere (-0.50 to -1.50) V 02.

May 17, vision of each eye was reduced to light of chart only, unimproved.

May 28 pilocarpine solution 1 per cent was prescribed three times a day to lower intra-ocular tension which had varied between 22 and 35 (Schiotz) in repeated trials.

June 3, further lens opacification had occurred with vision reduced to hand movements at 3 feet. Vision had thus decreased from 08 to hand movements in slightly more than one month. The patient is now awaiting cataract extraction.

CASE 2—A former eye patient, aged 37 in 1926 had vision in both eyes of 06 corrected to 10 by -0.37 sphere $\ominus -25$ cyl axis 180° . The lenses were clear and the fundi normal.

May 13, 1935 the patient appeared for examination apprehensive concerning her vision. She too had been taking dinitrophenol under careful medical supervision to reduce weight.

Examination showed V R E 08 with $+0.75$ sph $\ominus +0.50$ cyl axis 135° V 08 $+4$ V L E $+2.00$ sph $\ominus +0.12$ cyl axis 55° V 08 blurred. Near vision J 62 O U.

The marked change from a minus compound to a high plus compound in nine years is noteworthy particularly since the two refractions had been done under homatropine by the same observer.

The external eyes appeared normal. Fundus examination showed faint opacities in each lens. The slit lamp showed the same dry pebble-like anterior capsule noted in case 1 a few faint grayish opacities beneath the capsule some whitish flecks deeper, and a yellowish brown brass filing-like opacity in the posterior subcapsular layers.

May 20 she reported saying that vision had become much worse in the past few days. This was verified by the chart. V R E 06, with glasses 05. She preferred -0.50 sph to her previous lens V L E 07, with glasses 08-4. The subcapsular opacities in the right eye appeared more dense.

May 28, vision in the right eye was reduced to 01 partly unimproved by glasses. Vision L E 08-1 with $+1.00$ sph 08. Near vision R. none L J 200 with glasses J 62.

The right eye was markedly worse. The capsule appeared dry, as before. There was an increase in the steamy subcapsular opacities and those deeper in the cortex. Only a hazy reflex was obtained from the posterior layers. The left eye was apparently unchanged. The capsule appeared rough and dry. The subcapsular opacities remained faint. From here to the posterior cortex the lens was clear with the exception of a few scattered white flecks. The posterior subcapsular layers presented the same granulated brassy appearance with here and there a lighter more steel like glint showing dots and scratches.

May 29 a consultation was held with Dr Kaspar Pischel. Local measures consisting of ethylmorphine hydrochloride subconjunctival injections of physiologic solution of sodium chloride hot compresses forced fluids and the peroral administration of calcium were agreed on.

June 6 vision R E, light of chart unimproved. V L E 08. Prefers plano.

Further opacification had taken place in the right lens and a later extraction will be necessary. The left eye has remained unchanged. It has not become appreciably worse in three weeks' time.

CASE 3—A woman, aged 40, reported June 3 for examination, since she had been taking dinitrophenol and had known about cases 1 and 2. At the start of her treatment in July 1934 she had noted a transient blurring, but this had disappeared after a few doses. She had noted no further difficulty and had felt generally better (freedom from previous headaches) under her treatment.

Examination showed V R E 08 and J 50 in each eye. Refraction (homatropine) R E $+1.75$ sph $\ominus +0.25$ cyl axis 180° V 10-2 L E $+1.50$ sph $\ominus +0.25$ cyl axis 65° V 08+. The external eyes were normal. The fundus examination revealed bilateral faint lenticular opacities. The slit lamp showed the anterior lens capsule normal. There was no roughening apparent. Just beneath the capsule were seen faint grayish finely divided dots forming irregular precipitate-like strands. They made lacelike patterns. Occasional whitish cornmeal-like flecks were noted throughout the cortex. Posteriorly, just beneath the capsule, appeared yellowish brown, brass filing-like deposits similar to the appearance in the preceding cases. They showed considerable density. The vitreous appeared normal. These lenses showed the least changes that we have observed. Whether they will or will not increase is problematic. The patient is under careful observation.

Three more patients, aged 42, 43 and 52, who had received dinitrophenol have been examined. None of these showed the dried capsule, subcapsular opacification or the peculiar metallic sheen posteriorly. All of them showed occasional scattered, whitish, cornmeal-like flecks in the cortex, but as this is not uncommon in patients generally we have considered them negative. One patient showed bilateral faintly opaque zones in the lens periphery. These also are probably not specific changes.

AMOUNT OF DINITROPHENOL TAKEN

The following is an outline of the treatment with dinitrophenol for the purpose of weight reduction.

CASE 1—Mrs L, aged 50, was started on sodium dinitrophenol Oct. 20 1933, beginning with 100 mg daily and gradually increasing to 500 mg daily for a total dosage of 780 hundred milligram capsules and a total weight loss of $49\frac{1}{2}$ pounds (224 Kg) losing from $237\frac{1}{2}$ pounds (1077 Kg) to $188\frac{1}{4}$ pounds (854 Kg). The drug was discontinued from March 5 to May 17, 1934. A second course was given from May 17 to July 19 for a total weight loss of 17 pounds (77 Kg) and a total dosage of 229 hundred milligram capsules. The patient maintained her weight at approximately 160 pounds (72.6 Kg) until April 18 1935 when with a weight of 164 pounds (74.4 Kg), dinitrophenol was again administered in a dosage of 200 mg daily for one week, 300 mg daily the second week and finally 400 mg daily. At this point, dimness of vision was complained of and incipient cataracts were found. The patient received a total of approximately 1,072 hundred milligram capsules over a period of eighteen months.

CASE 2—Mrs A, aged 36, was treated continuously from Jan. 20 to July 24 1934, with a maximum dosage of 500 mg daily a total dosage of 910 hundred milligram capsules, and a total weight loss of $66\frac{1}{2}$ pounds (30 Kg) losing from $222\frac{1}{2}$ pounds (101 Kg) to 156 pounds (71 Kg). There was then a period of seven months without dinitrophenol and failure to follow dietary instructions with a resulting gain in weight of 44 pounds (20 Kg). The dinitrophenol was again administered on March 13 gradually increasing to a maximum dosage of 400 mg daily for a total dosage of 231 hundred milligram capsules and a total weight loss of 12 pounds (5.4 Kg). The drug was discontinued May 14 because of the finding of incipient cataracts in both eyes. This patient had a total of approximately 1,141 hundred milligram capsules of dinitrophenol over a period of sixteen months.

CASE 3—Mrs P, aged 30, started on sodium dinitrophenol March 1 1934 beginning with 100 mg daily and gradually increasing to a maximum of 500 mg daily for a total of approximately 316 hundred milligram capsules and a total weight loss of $21\frac{1}{4}$ pounds (9.6 Kg). The drug was discon-

tinued after June 26, 1934, but, with this relatively short period of treatment and small total dosage, definite lens changes are evident one year later

COMMENT

Three cases of cataract occurring in patients who have been receiving dinitrophenol as a weight reducer have been observed. The age of the patients and the absence of other external or physical factors suggest dinitrophenol as the cause. All three patients have shown posterior subcapsular opacities resembling brass filings, together with faint powdery, anterior subcapsular changes. Two of the three have shown a peculiar dried appearance of the anterior capsule. In these two the lens changes have been remarkably rapid in their development. In only one other condition, namely, frank traumatic cataract, have we seen lens fibers change so swiftly. In only one out of these four eyes has vision remained stationary for as much as three weeks. The others have progressed to blindness. The third patient has not been under observation long enough to determine progress. Since her opacities are the faintest that we have observed, the outlook may be better.

We shall not attempt an explanation of the effect of dinitrophenol on the lens in this report. This may be toxic, metabolic or dietary. It is known for a certainty that dinitrophenol does increase metabolism to a high degree and that it is possible to maintain this high rate during administration of the drug. It is conceivable that the lens changes result from this excessive burning up of body tissues.

Dehydration may be a factor, although this was carefully guarded against in the dinitrophenol administration. The hyperopia found at our first examinations, particularly when previous refractions had been myopic (case 2), suggests a thinning of the lens with decreased refractive power. If this is a drying out process, the roughened, dry-looking anterior capsule might follow. However, forced fluids in case 2 did not cause any appreciable difference either in the appearance of the capsule or in the disappearance of hyperopia as compared with case 1, in which less water was given.

Another possible explanation might lie in some food deficiency on account of the restricted diet these patients received. Particular care was given, however, to guard against this in the selection of their diets.

In six cases examined, in which dinitrophenol was taken for a considerable time, three showed lens changes of identical types. We are aware of lens changes in at least two other cases.

Under these circumstances, further use of dinitrophenol should be discontinued, pending further study on its secondary systemic effects.

384 Post Street

If Sugar Consumption Were Reduced.—It is estimated that, in the United States today, about one fourth of the energy requirement is met through eating sugar in its various forms. With this large proportion of the total energy intake in the form of such a one-sided food, it follows that the intake of protein, phosphorus, calcium, iron and vitamins is on the whole proportionately diminished. Investigations of recent years indicate strongly that this trend is contrary to good nutritional practices and that the American people would benefit if sugar consumption were reduced and the needed energy obtained from the consumption of other food materials. Probably the desire for sweet-tasting foods is best satisfied by the eating of fruits.—Sherman, H. C. *Food and Health*, New York, Macmillan Company, 1934.

Clinical Notes, Suggestions and New Instruments

THE USE OF FRESH HUMAN SERUM (COMPLEMENT) IN COMBINATION WITH THE ANTISERUM IN THE TREATMENT OF MENINGOCOCCIC MENINGITIS

REPORT OF TWO CASES

EDGAR C. FONDÉ, M.D., MOBILE, ALA.

In 1933 Bunim and Wies¹ directed attention to the use intrathecally of fresh human serum (complement) in the treatment of meningococcic meningitis. Report was made of one case in which on the thirty-sixth day of the disease, and after much antimeningococcic serum had been given, 15 cc. of fresh human serum was injected intrathecally, the spinal fluid, which had consistently grown meningococci, gave no growth forty-eight hours after its administration and convalescence proceeded uneventfully and completely thereafter. They cited thirty-one cases in which this treatment had been used and stated: "The literature of the last fifteen years has given no serious consideration to this addition in the serotherapy of meningococcic meningitis."

Since 1933 there has been no report in *THE JOURNAL* concerning the use of human serum in this disease. Rittenberg reported one case of influenzal meningitis with recovery in which this was given in addition to the treatment with anti-influenzal serum. Because of such striking improvement in both of the cases that I recently treated after the intraspinal administration of fresh human serum, I am reporting my observations to corroborate those of the others, and with the hope of focusing more attention on this procedure.

CASE 1—J. B., a white youth, aged 20, examined about 10 p. m., Jan. 5, 1935, was stuporous, opisthotonos was marked. The temperature was 103.6 F., the pulse 60 and the respiration rate 20. He showed all the characteristic symptoms and signs of meningitis. The illness began about noon, January 3, when the patient fainted in the postoffice. Persistent vomiting had been the chief complaint until the morning of January 5, at which time a severe headache developed. Rigidity of the neck, Brudzinski's and Kernig's signs and petechial rash were all present.

About 10 p. m. the spinal fluid showed 4,150 cells per cubic millimeter and many gram-negative intracellular and extracellular diplococci.

Conjunctival and intradermal tests for hypersensitization to horse serum were negative.

Thirty cubic centimeters of antimeningococcic serum was given intrathecally and 45 cc. of antimeningococcic serum intravenously. The patient's pulse and general condition became so grave during the intravenous administration that epinephrine was given and it was thought best to discontinue intravenous injections.

January 6 the patient's general condition was about the same. The temperature was 99 and the pulse 72. At 9:30 a. m. 20 cc. of whole blood² and 60 cc. of antimeningococcic serum were injected intramuscularly. Dextrose, 50 per cent, was given intravenously. Opisthotonos became very marked and at times the patient was delirious. At 8 p. m. spinal fluid showed 2,330 cells per cubic millimeter; no organisms were seen. Thirty cubic centimeters of antimeningococcic serum was given intraspinally.

January 7, the general condition was about the same, the patient was very rigid. The temperature was 100.6, and the pulse 75. Delirium persisted. At 11 a. m. 30 cc. of antimeningococcic serum was given intraspinally and 60 cc. of antimeningococcic serum intramuscularly. The patient was restless and delirious all day. At 8 p. m. spinal fluid showed

² Rittenberg, B. B. Influenzal Meningitis. Report of a Case with Complete Recovery. *J. A. M. A.* 102:1674 (May 19) 1934.

³ The whole blood and human serum used in these cases were obtained from a young man who had recovered from meningococcic meningitis in August 1934 five months previously.

2,560 cells per cubic millimeter, no organisms were seen. Thirty cc of antimeningococcic serum was given intraspinally.

January 8, the patient's general condition seemed a bit better. The temperature was 100 and the pulse 68. The spinal fluid showed the same gross appearance. There was some headache and marked rigidity. At 11 a. m. and again at 9 p. m. 30 cc. of antimeningococcic serum was given intraspinally.

January 9, the general condition of the patient was better. The temperature was 99, the pulse 60. At 3 p. m. spinal fluid showed 2,340 cells, this fluid grew meningococci on 1 per cent dextrose ascitic blood agar. Five cubic centimeters of antimeningococcic serum was given intraspinally and 12 cc of fresh human serum³ was given intraspinally.

January 10, the patient's general condition was much better. The temperature was 99, the pulse 60. Fifteen cubic centimeters of antimeningococcic serum was given intraspinally. Spinal fluid showed 1,800 cells.

January 11, the patient was complaining of puffiness of the lips and generalized itching. The general condition was still improving. At 10 a. m. the spinal fluid appeared almost clear, the cell count was 30, this fluid gave no growth.

January 12 and 13, the patient had a typical attack of serum sickness. No other spinal punctures were done. The patient's convalescence progressed uneventfully and completely.

On the fifth day of the treatment (seventh day of the disease) 12 cc of fresh human serum was introduced intrathecally, the spinal fluid withdrawn at that time grew meningococci. On the next day 15 cc of antimeningococcic serum was given. On the morning of the seventh day of treatment (ninth day of the disease) approximately forty-eight hours after the injection of the fresh serum, the spinal fluid appeared grossly clear (30 cells per cubic millimeter) and gave no growth. No other treatment was necessary.

CASE 2—B. A., a man, aged 24, white, was brought into the clinic unconscious, about 10 p. m., Jan. 13, 1935. The pulse was barely perceptible, the patient was very cyanotic and had a diffuse petechial rash and mottling of the skin. He appeared moribund. The history was that on the night before (January 12) he had ridden a freight train with friends from New Orleans to Mobile, during which time he complained of feeling very drowsy. On his arrival in Mobile, Sunday morning, January 13, he began vomiting and complained of a severe headache, which increased in severity throughout the day until about 5 p. m., when he became unconscious. Rigidity of the neck and Brudzinski and Kernig signs were present.

The temperature was 101.8 F (axillary), pulse 120 and respiration rate 32. The spinal fluid showed 8,500 cells per cubic millimeter and many intracellular and extracellular gram-negative diplococci. At 11 p. m. 30 cc of antimeningococcic serum was given intraspinally and 120 cc. of antimeningococcic serum intravenously. Caffeine sodiobenzoate $7\frac{1}{2}$ grains (0.5 Gm.) was given at the beginning of the serum administration.

January 14, the patient was semicomatose and could not respond to questions. The spinal puncture had to be done under chloroform anesthesia. At 11 a. m. 60 cc. of antimeningococcic serum was given intravenously. At 3 p. m. the spinal fluid showed 8,340 cells and many gram-negative diplococci; it grew pure culture of meningococci. Twelve cubic centimeters of fresh human serum was injected intraspinally, 5 cc of antimeningococcic serum was injected intraspinally under chloroform anesthesia, and 10 cc of antimeningococcic serum was injected intramuscularly.

January 15, the patient was definitely better in the morning. The temperature was 101 F (by mouth) and the pulse was 100. Three cubic centimeters of fresh human serum was given intraspinally, 15 cc of antimeningococcic serum intraspinally, 20 cc. of antimeningococcic serum intravenously and 10 cc of antimeningococcic serum intramuscularly. The spinal fluid at this time showed 8,560 cells, no organisms were seen; the fluid had a definite yellow tinge.

January 16, when I walked into the patient's room in the morning he asked me when he could get out of bed. The temperature was 99, the pulse 80. At 10 a. m. 30 cc of antimeningococcic serum was given intramuscularly. The spinal fluid showed marked improvement: 1,800 cells in forty-eight hours culture reported no growth.

January 17, 18 and 19, no other spinal punctures were done. Convalescence proceeded uneventfully and completely, except that the patient had a little serum sickness and a definitely gonococcic epididymitis developed (following catheterization at the onset of illness).

During the second day of the disease, 12 cc. of fresh serum was given intraspinally after thorough dosage of antimeningococcic serum. The patient was first seen on Sunday night, January 13, when he appeared almost moribund, on Wednesday morning, January 16, the last spinal puncture was done and the patient was definitely on the road to recovery. The spinal fluid taken at the time the human serum was introduced grew meningococci, within forty-eight hours afterward the spinal fluid gave no growth.

The rationale of alternately using fresh human serum with antiserum intrathecally is expressed by Kolmer.⁴ "Ordinarily, when we inject an immune serum we furnish but one bactericidal substance, namely, the bacterial amboceptor, and no complement at all. If the patient's complement is decreased or at least insufficient to activate the amboceptor furnished, lysis will not occur, and accordingly an increased therapeutic effect may be secured by the injection simultaneously of an immune serum and fresh normal serum."

Of course when antiserum is given intravenously there is no need, particularly at the beginning of a disease, to supply complement, for it is already present in the patient's serum. But when antiserum is given intraspinally there is no complement present, for spinal fluid contains little or no complement. Kolmer and others⁴ have shown that the addition of fresh serum to antimeningococcic serum definitely increases bactericidal power and opsonic activity. In other words the bactericidal effect of amboceptor (supplied in the antiserum) is more effectual and phagocytosis is definitely increased.

In the two cases reported I believe that the change of the spinal fluid to yellow indicated that this had taken place and that lysis was more extensive.

Bunim and Wies recommended that 5 cc of fresh human serum be added to 15 cc of commercial antiserum and given intraspinally.

I recommend that the fresh human serum (15 cc or a quantity slightly less than the amount of spinal fluid withdrawn) be given within twenty-four hours following the initial intravenous and intraspinal injections of antiserum and that this in turn be followed within twenty-four hours by more antiserum. In other words, the sequence and kind of treatment similar to that used in the second case report is recommended for the reason that it has been shown that an excess of antiserum (amboceptor) may reduce the degree of bacteriolysis. Neisser and Wechsberg⁴ explained this by stating that the amboceptor absorbed a portion of the free complement and thus prevented this portion from combining with those amboceptors united with bacteria (complement deviation).

Since the advent of antimeningococcic serum in the treatment of meningococcic meningitis the death rate has been reduced from 70 to 80 per cent to 30 to 40 per cent (Stevens). Rationalizing consistently on this result along the lines of immunology suggested in this discussion it would seem that a great factor in causing the reduction is the early administration of ample amounts (from 100 to 120 cc) of antiserum intravenously. The antiserum that has been given intraspinally has been effectual but not as effectual as it could have been if a complement had also been added. It has been shown that bacteria grown in their homologous antisera become avirulent and microbic dissociation takes place.¹ The case reported by Bunim and Wies demonstrated this, which condition is not an infrequent experience in the treatment of the disease.

CONCLUSION

In two cases of meningococcic meningitis, at different periods during the course of the disease 15 cc of fresh human serum was given intraspinally, preceded and followed by the administration of commercial antiserum. Within forty-eight hours after its injection the spinal fluid of both patients became sterile. In the second patient who appeared more critically ill

⁴ Kolmer, J. A. Practical Textbook of Infection Immunity and Biologic Therapy. Philadelphia: W. B. Saunders Company, 1923.

the fresh human serum was injected within twenty-four hours following the initial administration of the commercial antiserum, and in this case convalescence and recovery occurred more rapidly.

Observations in these two cases, together with the reports in the literature, justify the opinion that the use of fresh human serum intraspinally is a distinctly valuable addition to the serotherapy of meningococcic meningitis.⁵

INTRAPELVIC PROTRUSION OF THE ACETABULUM (OTTO PELVIS)

WALTER N. LEVIN, M.D., FRESNO, CALIF.

Until recently, intrapelvic protrusion of the acetabulum had not been reported in American literature. Though first described by Otto¹ in 1824, the first report in this country did not appear until 1922 when Hertzler² reported one case. Since that time cases have been recorded by Lewin,³ one case, Doub,⁴ eight cases, Pomeranz,⁵ seven cases, Nichols and Shifflett,⁶ two cases and Schaap,⁷ two cases. In all, approximately sixty-five cases of true Otto pelvis have been reported, and the majority of these in the foreign literature.

Because of its rarity another case is here reported, with a brief review of the disease.

Intrapelvic protrusion of the acetabulum is a condition characterized clinically⁸ by pain and limitation of motion in the hip. This restriction of motion is particularly noted in abduction and rotation, and often in adduction, flexion and hyperextension. Muscular atrophy of the thighs is not uncommon, and a peculiar gait described as waddling or wabbling is present in late cases. The disease may be unilateral or bilateral.

Roentgenologically⁹ there is a deepening of the acetabulum with a medial displacement and thinning of its inner wall. The femoral head also shows changes but these changes are less marked. The general contour of the head may be retained but there is usually an irregularity of outline and a thinning of the articular cartilage. The joint space is narrowed. The greater trochanter is much closer to the ileum and, in advanced cases, may impinge on it.

The etiology is unknown. Most writers agree that it is not a disease entity but rather a disease process. Lewin³ believes that it is due to a combination of factors, which are "(1) hypertrophic arthritis of the hip joint, (2) weakening of the acetabular floor, (3) trauma due to weight bearing or injury and (4) muscular contraction forcing the head of the femur against the acetabular floor." Pomeranz⁵ and Schaap⁷ both report cases that seem to be due to the gonococcus. Golding⁹ reports a case in which he believes that the most likely cause is a disturbance in growth, a late ossification of the cartilages that make up the acetabular floor and the constant pressure of the femoral head being enough to produce the protrusion (Eppinger's theory). Rheumatic infections seem to be the cause of a number of cases. Intrapelvic acetabula attributable

to gross destructive processes, such as tuberculosis, syphilis, malignancy, osteomyelitis and fracture, are not true Otto pelvis.

The prognosis⁸ in this condition is poor. Ankylosis ultimately occurs, with a resultant disappearance of pain.

Only two references were found regarding treatment. Lewin³ recommends removal of the foci of infection and then orthopedic treatment. This consists principally of absolute bed rest, the application of Buck's extension, local applications to the hips for pain, and the application of a plaster cast. In unilateral cases the patient may be allowed on crutches after a 2 inch block has been put under the shoe of the opposite side. Schaap⁷ reports two cases due to the gonococcus that improved with autovaccines.

REPORT OF CASE

B. A., a white girl, aged 13 years, had been fairly well most of her life, except that she had always been thin and frail. She had had smallpox but no other illnesses and had had no injuries. She was a normal full term baby, breast fed for five months and then given Eagle Brand milk. She had orange juice since she was 1 month of age but had no cod liver oil. She has not yet begun to menstruate.

The family history is negative except that one of her sisters has diabetes mellitus.

The first appearance of any joint abnormality occurred in April 1934, when the patient found that she could not ride a horse because she could not spread her legs far enough apart to straddle it. However she made no mention of this incident

Roentgen appearance of the hip joints showing deepening and medial displacement of the acetabula and irregularity of the femoral heads.

to her parents. She had played with other children without suspecting that anything was wrong. In September she began to complain of pain in the thighs after walking or standing for any length of time. Her parents thought that she had rheumatism and took her to a chiropractor in November. She became progressively worse and began to walk "stiff-legged." She was finally taken to a physician and he referred her to the county hospital Jan. 11 1935.

The patient was thin and underdeveloped but did not appear acutely ill. She had a peculiar wabbling gait and her knees seemed to get in the way when she walked. She had a marked lordosis and a slight genu valgum. There was no evidence of rickets. The head was normal. The tonsils were cryptic but not grossly infected. No adenopathy or other abnormality of the neck could be found. The heart and lungs were normal. The abdomen was normal. Both upper and lower extremities were thin and their musculature was underdeveloped but in keeping with her general state of nutrition. Both hip joints were markedly limited in motion in all directions but more marked on the right side than on the left. The motion as measured was as follows: Abduction in the left hip was 8 degrees from the midline, and in the right hip 6 degrees; adduction in the left hip was 30 degrees from the midline, and in the right hip 18 degrees; flexion of the left hip was 45 degrees and of the right hip 25 degrees; hyperextension of the left hip was 15 degrees, and of the right hip none. Rotation was estimated to be about one fourth normal in the left hip and none in the right hip.

5 I do not consider as most important the fact that in both of these cases I used convalescent human serum. It is true that the volunteer was bled about the same time horses are bled for the antiserum but because of facts already mentioned and because I used such small amounts of convalescent serum I do not feel that the serum of the convalescent is at all necessary or more important than supplying complement. Of course if convalescent serum is at hand I recommend its use.

From the orthopedic department of the General Hospital of Fresno County.

8 Hertzler, A. E. Lewin, P. Doub, H. P. Golding, F. C. Protrusion of the Acetabulum (Central Luxation). Brit. J. Surg. 22: 56 (July) 1934.

Laboratory observations were as follows. The urine showed some pus cells in the voided specimen but otherwise was normal, the blood showed hemoglobin, 75 per cent (Dare), red blood cells, 4,350,000, white blood cells, 6,000, with 61 per cent polymorphonuclear neutrophils and 39 per cent lymphocytes, the blood Wassermann reaction was negative, the blood calcium was 9.8 mg per hundred cubic centimeters, and the Mantoux test was negative up to 1 mg.

Roentgen examination of the lungs showed them to be normal. The x-ray plate of the hips is reproduced here and is typical of the condition. The skull, shoulders, spine, knees and wrists were also examined roentgenologically and were considered to be normal.

1060 Fulton Street

TYPHOID ABSCESS ABOUT LOWER END OF STERNUM

JAMES A. GANNON, M.D., WASHINGTON, D. C.

Miss G., aged 41, a government employee, consulted me, Oct. 30, 1934, because of pain beneath the lower extremity of the sternum. Her family history was unimportant. Her previous history showed that she had been ill with typhoid from September 1927 to January 1928. During this illness she lost 30 pounds (13.6 Kg.). During the progress of typhoid pain developed in the chest, the exact area of which she did not remember. The pain troubled her continuously throughout her illness. In March 1928 a roentgenogram showed an abscess in the neighborhood of the sternum, which was drained and which contained typhoid bacilli. A sinus formed and drained until Aug. 17, 1928, at which time it was excised at the Letterman General Hospital in San Francisco.

Notes furnished by the hospital stated that under local anesthesia a small elliptic incision about 1 inch long running transversely was made around the sinus, which was located just to the right of the sternum over the sixth intercostal space. The sinus had been previously injected with methylene blue. It was excised and found to run down between the costal cartilages to the right side of the sternum. When this sinus was excised down below the ribs where it came in contact with the pleura, no communication with an infected rib or sternum could be found. It was not thought wise to explore the sinus further. The wound was left wide open and packed with iodoform gauze.

She was discharged from the hospital with the wound still draining, September 1, and was readmitted Jan. 4, 1929, complaining of a discharging sinus of the right side of the chest which dated back to the fall of 1927. At this time the sinus tract was injected with methylene blue and broadly excised. It was found to go down to the ensiform cartilage which was gradually sloughing away. The ensiform cartilage was removed in its entirety and a small involvement in the lower portion of the sternum was thoroughly curetted. The cavity was packed with iodoform gauze and the skin wound closed about it. She was discharged January 28 with a small sinus which was cleared up in a short time. Since March 1 the patient had enjoyed good health and had no trouble in the chest wall until she consulted me Oct. 30, 1934. Examination by me on this date showed that she was fairly well nourished and developed and appeared to enjoy good health. The tonsils had been removed. The teeth were in good order. There were no palpable glands in the neck, axillae or inguinal regions. The lungs showed no abnormality, the heart sounds were normal, the pulse was 80 and the temperature was 98.6 F. There was no tenderness or abnormality of the abdomen and she said that her menstrual function was normal and painless and that she felt well in every respect except for pain in the lower end of the sternum. There was an irregular scar with keloid tendency running from a point 1 inch above the ensiform cartilage downward and to the left to a point 1 inch below the ensiform cartilage. There was no redness or edema of the skin. There was no dullness on percussion, but there was pain on pressure over this area. Hot applications were advised and a roentgenogram was taken by Dr. Bierman on the following day. Dr. Bierman reported that roentgen examination of the sternum showed no evidence of such changes as would be seen with a recent osteomyelitis neoplasm or other similar pathologic

condition. The costal cartilage in this region was considerably calcified, but no other abnormalities were noted. The conclusion was that the sternum was apparently normal, with marked calcification of the costal cartilage.

I did not see the patient again until December 5, at which time she called on me with a definite abscess pointing just below the sternum. She said that the reason she did not call on me following her recent interview was that the pain had disappeared promptly after the roentgen examination and that it had just returned. The abscess was aspirated, and a culture was made after which the abscess was incised and drained. Dr. Cajigas reported that the culture contained a pure strain of typhoid bacilli and he made a vaccine from it. The patient was isolated in a hospital and cultures of the feces, blood and urine were made. The typhoid organisms were not found in any of the tests. The vaccine was injected subcutaneously in gradually increasing doses every three days and complete healing had taken place on Jan. 15, 1935. The patient has returned to work apparently well. Subsequent roentgenograms of the ribs and spine failed to show involvement of these bones.

This case is reported because of the long quiescent period, nearly six years, because of the inability to find bone involvement and because of the rapid recovery under vaccine treatment.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

PHYSIOLOGY OF THE PARATHYROID

ADOLPH M. HANSON, M.D.
FARIBAULT, MINN.

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed.

The parathyroid glands are concerned with calcium-phosphorus metabolism. Experimental work with animals indicates that calcium-phosphorus metabolism is of great importance in the body because it is necessary to the calcification of bone and teeth. The ionic calcium of the blood serum serves to control the varying normal degrees of irritability of nerve and of voluntary, as well as of involuntary, muscle. Because of this effect on the nerve endings and the involuntary muscle, it also increases vascular tone. It plays an important role in the clotting of blood and milk. That portion of the nonionized calcium which is diffusible may play its part with the ionized form in lessening the irritability of nerve endings and muscle.

Contrary to popular opinion at the present time, little is known concerning these glands so essential to life, in fact, only recently the claim has been made that they are not essential merely because parathyroidectomized animals are found to develop normally and to survive a complete reproductive cycle when given vitamin D. As complete parathyroidectomy is well nigh impracticable these statements can be taken only as opinions probably lacking in the basis of demonstrable fact.

The parathyroids are peculiar to vertebrates with the exception of the Actinopteri which include the known fishes of today. These little glands are classified as external and internal, or superior and inferior, and develop from the posterior pouches of the third and fourth branchial clefts. The external glands are usually

found outside the capsule of the thyroid gland in the higher vertebrates. The internal glands may be found within the thyroid in the bovine species and in man, or both the so-called external and internal parathyroids may be centrally placed within the thyroid lobe, as may occur in the canine, or all may be outside the thyroid, as in the albino rat, where the four parathyroids are arranged along the upper border of the thyroid and attached to it and to one another, the external ones being the larger. Accessory parathyroids are common and may be found along the course of the carotid artery in the neck and upper mediastinum as separate glandules, or these may occur as inclusions in the thyroid and in the thymus. The thymus inclusions are undoubtedly quite common.

The parathyroids originating from the third branchial clefts migrate lower than those budding from the fourth and are found in close association with the inferior thyroid arteries. The thymus originates from the anterior pouches of the third and fourth branchial clefts and, in close association with the parathyroids, the thymus anlagen descend in the neck, the portions springing from the third clefts descending lower than those from the fourth clefts, as is the case with the parathyroids. This explains the frequency with which aberrant parathyroids have been found as inclusions in the thymus of lower animals. It has been demonstrated that parathyroid inclusions occur in the cat thymus in 50 per cent of the animals studied. A recent report¹ indicates that parathyroid inclusions are found in the human thymus far more frequently than was formerly thought. Parathyroid inclusions have been found in the cervical as well as in the thoracic thymus in man. The most that can be expected, then, even with a total thyroparathyroidectomy, is a temporary and incomplete hypoparathyroidism of varying degree in each individual animal so operated on, owing to the removal of most of the normally active parathyroid tissue. This alone is sufficient to cause death in most animals when no means are taken to increase the blood serum calcium. It has been found in operative work on dogs that certain breeds survive complete thyroparathyroidectomy without exhibiting any drop in the blood serum calcium and without treatment of any kind. The logical conclusion is that active accessory parathyroids exist in these animals and are ample to the needs of the body in these isolated instances.

The parathyroid contains two types of cells¹ the principal cell and the oxyphile cell. The parathyroid "principal cell" is a large cell with a clear, faintly staining cytoplasm and a vesicular nucleus. The "oxyphile cell" is also a large cell with eosinophile granules in the cytoplasm and a small round, or slightly oval, deeply staining nucleus, centrally placed. This would indicate that the parathyroid has at least two functions, namely, control of calcium-phosphorus metabolism and another as yet unknown. Which cell is extracted by boiling in hydrochloric acid and the active element of which is now known as one of the parathyroid hormones is not yet known.

Calcium-phosphorus metabolism is not only concerned with the increase of ionic and dialyzable calcium in the blood serum and its normal retention and application to the needs of the entire body, but in maintaining the

normal calcium-phosphorus balance in the amounts of each within the normal varying degrees of their interrelationships. The parathyroids subserve this function, and when the so-called external and internal parathyroids have been removed the aberrant parathyroids hypertrophy and carry on this function sufficiently to maintain life, provided the operated animal survives that long. It is well known that the fetus is a calcium phosphorus robber during gestation and lactation, and nature may have provided these accessory parathyroids for the purpose of meeting this as well as accidental demands.

The normal amount of calcium in the blood serum in man is generally accepted at from 9 to 11 mg per hundred cubic centimeters, that of inorganic phosphorus,² as an average upper limit of normal, at about 6 mg per hundred cubic centimeters.

Hypoparathyroidism and hyperparathyroidism, while they do not strictly belong to a discussion of parathyroid physiology, are briefly mentioned, as it is from viewing the abnormal that one may draw probable conclusions concerning the normal. In parathyroid dysfunction due to a deficiency of calcium in the blood serum, varying degrees of hyperexcitability of nervous tissue and muscle may occur, the extreme degree being the clinical entity known as tetany. It has been estimated that 90 per cent of the convulsions in children under 2 years of age are due to this condition. Hyperparathyroidism, on the other hand, increases the viscosity of the blood and depletes the calcium of the osseous system. It may rightly be said that the normal function of the parathyroid is to preserve a normal nervous system and normal muscle contractility, including that of the heart, and to bring about and maintain the normal calcification of bone and the calcification of pathologic areas in healing processes.

The action of phosphoric acid on creatine is accompanied by the formation of certain by-products, including methylguanidine, which is toxic in large amounts. It is reasonable to surmise that in parathyroid dysfunction methylguanidine may occur in sufficient concentration to be toxic. Experimental work and certain clinical observations suggest a detoxifying effect following the injection of active parathyroid extracts. This is still a moot subject that cannot be affirmed or denied until scientists have completed their studies. The role that the parathyroids may play in maintaining natural immunity and normal healing power awaits scientific proofs to explain certain clinical observations.

As the early references to the parathyroid are so generally well known and because of the thorough review of the subject by Thomson and Collip,³ including more than 500 references, I feel that this short discussion concerning the physiology of the parathyroid calls for no more than a plain statement of facts and a passing mention of certain probabilities.⁴

² While the inorganic phosphorus content may be stated as 6 mg per hundred cubic centimeters for the upper limit of normal it would be more nearly correct to place the average upper limit of normal at about 5 mg. The average normal content of inorganic phosphorus of the blood serum has been variously estimated between 2.5 and 4 mg per hundred cubic centimeters in the human being on an average diet. For instance, Hunter (Quart J Med 24 393 1931) states 2.5 to 3.5 mg per hundred cubic centimeters to be the normal range with levels up to 5 mg in children. Key and Byrom (Brit J Exper Path 8 240 1927) consider the average normal to be 2.9 mg in females and 3.1 mg in males.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED

THERAPY OF PSORIASIS

OUTLINE BY DR. THEODORE CORNBLEET

There is no disorder more capricious in its responses to therapeutic measures than is psoriasis. Remedies that at one time are effective are valueless at another in the same person. The mildest agents may be helpful at first, and then the most powerful may not suffice to make an impression on the condition when it has reached an intractable state. There are no specifics and no known causes to attack. Out of the almost countless number of remedies proposed, only a few are worthy of mention as being relatively dependable.

One of the characteristics of psoriasis is the recurrence of the eruption at intervals. The periods of freedom may range from only a few weeks to many years. The aim of the treatment is then to clear up the eruption that is present. No promise for the future can be safely made. The treatment must be carried out in a thorough fashion until every trace of the lesions is removed. Any remaining lesions predispose to an early recurrence. As with many other dermatoses, the attack on psoriasis is by both general and local measures.

GENERAL MEASURES

The patient is given a thorough physical examination, and anything abnormal is corrected. The treatment for the skin condition itself proceeds as follows:

1 *Diet*—A low protein diet has been advocated by many, who believe that it is helpful to reduce or entirely

Low Fat Diet

Forbidden	Allowed
All greasy soups	Lean soups (fat removed after letting it get cold)
All sausages and delicatessen except frankfurters made of lean meat	White of egg
All fat meats such as pork, mutton, fattened chicken, duck, goose, eel, herring, salmon, carp and other rich fish, roe and egg yolk.	Lean beef (roast beef, boiled beef and so on)
All cheeses except cottage (cream) cheese	Lean veal, lean venison (rabbit, deer and the like), lean ham.
All fats (bacon, butter, fat, palm, margarine, oil, cream, butter, whole milk, buttermilk and the like)	Lean fowl (squab, chicken, partridge)
Meat may be roasted with some butter, but the fat must be removed from the gravy by letting it get cold.	Lean fish (pike, cod, pickerel and others)
Cakes, cookies, whipped cream, butter, cookies	Sugar, malt, honey, raspberry juice and other fruit and berry juices
	All kinds of fruit and berries raw or preserved
	Flour, rice, cream of wheat, potatoes, macaroni, noodles
	All kinds of vegetables prepared without butter or fat
	Bread, white or rye bread, zwieback, toast, rolls
	Skim milk

eliminate animal foods, including in this meat, eggs, poultry and fish, and in addition to forbid the use of peas and beans and fermented cheese. Recently a low fat diet has been advocated as more rational, because it is believed that in the psoriatic patient a disturbance of fat metabolism exists. Fat should be restricted to 20 Gm a day (10 Gm for children) including the fat

used for cooking, and such diet must be continued for many months, as the effect does not appear for weeks or months and a relatively low fat diet must be continued indefinitely, as the psoriatic predisposition persists. The weight must be watched.

2 *Climate*—Psoriasis is generally worse or it recurs during the winter season and usually improves with the appearance of warm weather. Many patients improve when they go to a warm, equable climate, and they may thus at times prevent the recurrences that they otherwise get with the advent of cold weather. Psoriasis does, however, occur in warm climates, but it is less prevalent in these. A resident in a warm climate may derive benefit from a temporary change in residence even if it be to a colder one. A change in environment often is helpful even if only temporarily. A sea voyage or a trip to the seashore is said to be particularly helpful.

3 *Drugs*—(a) Arsenic is, of all the internal remedies advocated, the most important. It sometimes will clear an eruption without the aid of local applications. It should never be used with an acute or progressive eruption. It should be used only when the eruption has become subacute or chronic or is stationary. As arsenic may lead to unfavorable changes when long continued, it should be used only at intervals. It is well to start with a small dose and to increase the dosage up to tolerance. When symptoms such as puffiness of the eyelids, edema of the ankles or gastro-intestinal disturbances, are seen the dosage should be slightly reduced. There are some who believe it should be used only as a last resort, because it may lead to such untoward results as keratoses and epitheliomas, as well as to other damage. Solution of Potassium Arsenite (Fowler's solution) is the form of arsenical mostly used. Commencing with a dosage of three drops in water twice a day, this is increased by one drop each succeeding day until a maximum of from 10 to 15 drops is taken or until symptoms of intolerance appear. After a three months use it is well to give the patient a rest from arsenic. It may be recommenced after a two to three months interval. One should always write "do not repeat" on the prescription, for many cases of chronic arsenic poisoning result from unsupervised continuance of the drug.

(b) Salicylate is held in high favor, particularly in early acute cases with considerable itching, in which arsenic is contraindicated as it makes the itching worse. Sodium salicylate is generally used. It is prescribed in doses of 0.6 Gm with an equal amount of sodium bicarbonate to be taken freely diluted three times daily (prescription 1).

(c) Alkalis are used by many and are particularly favored in gouty or rheumatic subjects. They may be combined with salicylate (prescription 1).

PRESCRIPTION 1—Salicylate and Alkali

R	Sodium salicylate	10.00 Gm
	Sodium bicarbonate	10.00 Gm.
	Cinnamon water	60.00 cc.
	Syrup of cinnamon (N. F. VI)	to make 120.00 cc.
M	Label: Two teaspoonfuls in water three times daily after meals (in acute itching stage)	

(d) Of other alteratives, antimony is sometimes of service in acute progressive cases. Other agents that have been recommended are colchicum, potassium iodide and mercurous iodide. Arspheamine has been advocated by some but, except when there is a coexisting syphilis, it is questionable whether its use is justified.

Thyroid and pituitary are said to be of value. As will be seen, there are many possible remedies but there is no reliable one.

4 "Proteotherapy"—(a) Autohemotherapy. This method has gone through alternating periods of great favor and disfavor in psoriasis. Some feel that by itself it will clear many of the eruptions. There can be no question that at times it is of distinct benefit and that it often increases the effectiveness of other remedies. Twenty cc of whole blood is removed from the vein and injected intramuscularly, before clotting, generally into the gluteal region, every fifth day.

(b) Autoserotherapy. Blood, 50 cc, may be removed, allowed to clot and centrifugated under sterile conditions. The serum is then injected intramuscularly or intravenously.

LOCAL THERAPY

General measures alone usually do not suffice to clear up an eruption. They require the aid of local applications.

1 *Removal of Scales*—The removal of scales that have accumulated on the lesions and offer an inert barrier to the effective action of the medicaments must precede all local treatment. It may be accomplished by daily warm baths with Linniment of Soft Soap ("tincture of green soap") and water. An alkaline bath, made by dissolving one or two tereupfuls of sodium bicarbonate in the bath, assists in the process. Following the bath the softened scales are brushed off with a turkish towel. A stiff brush may be required to complete the removal of the scales. The skin may become dry as a result of this process and some bland grease or oil may be rubbed into the skin which also helps to soften and remove the scales. Salicylic Acid 5 to 10 per cent in Petrolatum (prescription 2) applied to the lesions is particularly helpful toward removing obstinately adhering scales.

PRESCRIPTION 2—Salicylic Acid Ointment

Rx	Salicylic acid	3.00 Gm
	Petrolatum	30.00 Gm
M	Label: Apply locally over night (to aid in removal of scales)	

2 *Soothing Applications*—Care must be used in the acute types or in the generalized forms not to use too stimulating an agent lest the skin be irritated and the eruption converted into an exfoliative dermatitis. In psoriasis, salves act better than lotions. In the acute forms a soothing ointment, such as Ointment of Rose Water ("cold cream") or Boric Acid Ointment, is likely to be found useful. As the eruption becomes less acute, more and more stimulating medicaments may be added, but the action of such applications should be closely watched and they should be promptly discontinued and bland ones substituted with the first signs of extension of the eruption or irritation of the surrounding skin.

3 *Irritative Applications*—These for the most part are reducing agents. The preferred ones are powerful.

(a) Chrysarobin is one of the most effective. Chrysarobin itself should not be used on the hands, face or scalp because it colors the normal skin deep brown and the hair yellow and it produces conjunctivitis. It may be used in ointments with Petrolatum as the base in strengths of 1 to 10 per cent. After the application has been made to the lesions, it is sprinkled with Talcum. After several days (from one to ten days, with an average of five days) the surrounding skin is seen to have become reddened. The

chrysarobin ointment is then discontinued and a bland one used instead, such as Zinc Ointment or Boric Acid Ointment. As Chrysarobin is irritating not only to the skin but also to the kidneys, patients having extensive application of this agent must be closely supervised. Discutient (scale removing) and irritative treatment may be combined as in a compound chrysarobin and salicylic acid ointment (Unna and Dreuw) useful for local scaly patches (prescription 3). From one to three days following the application of this ointment a brownish crust forms on the surrounding skin and the patches of psoriasis scale intensely. Bland ointment may then be used together with baths to remove the crusts and scales. After a few days the chrysarobin preparation may again be used, to be followed as before by simple oils or greases. Several such alternations are usually effective.

PRESCRIPTION 3—Compound Chrysarobin and Salicylic Acid Ointment

Rx	Salicylic acid	10.00 Gm.
	Chrysarobin	
	Oil of cade	of each 20.00 cc
	Soft Soap	
	Petrolatum	of each 25.00 Gm.
M	Label: Apply to patches (Useful on subacute scaly lesions)	

Less efficient than the ointments of chrysarobin are the chrysarobin varnishes. These have the advantage, however, that they may be better confined to the lesions themselves and help to spare the clothing, which otherwise is discolored a mahogany brown stain that requires chlorinated lime or benzene for removal. A 7 per cent solution of chrysarobin in chloroform may be painted over the lesions. When the chloroform evaporates, a fine powder remains, which is then covered over with flexible collodion. Simpler but less effective is a 7 per cent solution of chrysarobin in "traumatin," which is a 10 per cent solution of gutta percha in chloroform to which 2 per cent of salicylic acid may be added. When the films begin to peel, they are removed and replaced with a new application.

(b) Tars of various types, such as wood tar, oil of cade or coal tar are preferred by some physicians, who no longer use chrysarobin because of its obvious disadvantages and because it may vary in its effectiveness from sample to sample. The tars may be used in 5 to 10 per cent strengths in Zinc Ointment or Paste of Zinc Oxide (Lassar's Paste). They may be put in flexible collodion in somewhat greater strengths, from 10 to 20 per cent. Tar may be used with other agents such as Sulphur or Soft Soap as in the long used Compound Sulphur Ointment (Wilkinson's ointment).

They may be used in liquid form and undiluted but are usually best dissolved in alcohol in 10 to 25 per cent strengths and Salicylic Acid 5 to 10 per cent, and Soft Soap 25 to 50 per cent may be added (prescription 4). The liquid form may be painted over the patch after removal of the scales following a bath. When the liquid tar preparation has dried for a while,

PRESCRIPTION 4—Salicylated Oil of Cade Pigment

Rx	Salicylic acid	10.00 Gm.
	Oil of cade	25.00 cc.
	Soft Soap	25.00 Gm.
	Alcohol	to make 100.00 cc.
M bath	Label: Paint over patches permit to dry and wash off excess in	

the patient may be returned to the bath and the excess of tar finally washed off. It is always well to begin the use of tar preparations with the weaker concentrations and build up to the stronger, because they may at times surprise one with an unexpected reaction, for

the tars may produce toxic symptoms, such as vomiting and diarrhea, and kidney irritation. These promptly disappear when the application is removed. Betanaphthol and Resorcinol may be looked on as colorless tar succedanea, to be employed in 5 or 10 per cent solutions or ointment when the colored tar preparations are objectionable.

(c) Ammoniated Mercury is mostly used for the scalp. The strength is 10 per cent, and a base is used that will wash out of the scalp readily, such as rose water ointment. Salicylic acid may be incorporated to advantage in proportions of 3 to 5 per cent. Such an ointment (prescription 5) may also be used on the glabrous skin. The urine should be watched for signs of kidney irritation.

PRESCRIPTION 5—Ammoniated Mercury and Salicylic Acid Ointment

R	Ammoniated mercury	3 00 Gm
	Salicylic acid	5 00 Gm
	Rose water ointment	30 00 Gm
M	Label	Apply to scalp

4 **Irradiation**—(a) Ultraviolet rays are most useful in the acute types of psoriasis as well as in the superficial types in folds. Some believe that their use at intervals, after involution of an eruption by other measures such as x-rays, may materially prevent recurrences. The exposures should be given twice weekly and to the point of obtaining definite reactions with pigmentations. This method is not quite so effective as that with the x-rays but is free from possibility of dangerous sequelae. A method that has been particularly effective is the combined use of 1 to 5 per cent coal tar ointment with ultraviolet rays. The ointment is spread on the skin about one-eighth inch thick. At daily intervals the excess ointment is wiped off with olive oil, a thin film of the crude coal tar being left. Irradiation with a mercury quartz lamp is then carried out. This is said to be particularly effective in the exfoliative dermatitis following psoriasis. This form of treatment should be carried out only in a hospital or where the patient can be closely supervised, but in modified form it can be used for ambulatory patients.

(b) When judiciously used, roentgen therapy is effective, painless and clean and requires no care on the part of the patient. Once he learns of it, he is apt to want it in preference to all other remedies. Its excessive use, however, is dangerous. Psoriasis is usually a recurrent disease and the repeated use of x-rays over an area is liable to lead to serious sequelae such as telangiectasis, keratosis and epitheliomatous degeneration. If from four to six weekly doses of a quarter unit (75 roentgens) are ineffective, it is wisest to discontinue the x-rays, as the eruption is apt to be resistant to further exposures. On the scalp it is perhaps best to employ weaker doses of about one-eighth unit (38 roentgens) once weekly. For the nails a quarter unit of filtered rays to the tip of the finger as far proximally as a half inch from the cuticle is most effective. Strong local remedies should not be used in conjunction with the x-rays. A 5 per cent ammoniated mercury ointment may generally be used with safety. Some believe that the psoriatic skin is more sensitive to x-rays than the normal. As with other dermatoses, dosage should be reduced for patches occupying the more tender skin in the folds such as submammary and axillary. Psoriasis of the auditory canals may be treated with 0.5 unit filtered rays at intervals of two to three weeks. The surrounding skin should be carefully shielded. At times, lesions of psoriasis may

involute promptly and recurrences be resistant, while x-rays are ineffective in some from the start. If roentgen treatment is persisted in without effect, the lesions are apt to become resistant to other measures as well, and increasing the dosage to obtain results leads to dangerous sequelae. X-rays should not be employed in eruptions that recur quickly or that are acute and spreading.

(c) Radium is of limited use in psoriasis. It is valuable in tube form in such places as the auditory canal. A silver tube screened with rubber and placed within the canal to give from 40 to 50 millicurie hours generally produces excellent results.

(d) W-rays or grenz rays may be useful for hairy parts or where the underlying tissues may be injured by x-rays, such as the testes. The dosage should be such as not to provoke sharp reactions.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

CAMP SUPPORTS ACCEPTABLE

Manufacturer S. H. Camp and Company, Jackson, Mich.
The following supports are available:

VISCEROPTOSIS SUPPORTS Visceroptosis supports are designed to aid in holding the ptosed organ or organs in more nearly normal position, to be used on recommendation of physician in conjunction with other treatment.

PRENATAL SUPPORTS Certain obstetric patients with thinned, overstretched abdominal walls, or exceedingly pendulous abdomens, may require supports. When ordered by a physician these are available both for support and for relief of the often accompanying backache.

POSTNATAL AND POSTOPERATIVE. When prescribed by the physician in cases needing support, postpartum supports are designed to coordinate clinical needs of the physician with comfortable support of the patient. Postoperative garments are very often used after operation on obese subjects, in cases of drainage and in those cases in which suppuration has taken place.

HERNIAL SUPPORTS These supports are recommended for selected umbilical, ventral (incisional) or inguinal hernia, when such are of sufficient size as to require support, and when operation is contraindicated, refused or postponed for a time. The selection of the proper case for such support is left to the physician.

SACRO-ILIAC SUPPORTS These supports are designed to protect and to limit the motion of the sacro iliac joints and are to be sold only when prescribed by a physician.

MAMMARY GLAND SUPPORTS Mammary gland supports, bust slings or brassieres are designed to support sagging or pendulous breasts, also in the enlargement of the mammary gland during the antepartum period and during lactation.

LUMBOSACRAL AND DORSOLUMBAR SUPPORTS These supports are designed to protect and to limit the motion of the dorso-lumbar and lumbosacral region when less complete immobilization than that afforded by plaster-of-paris casts. Leather jackets and specially designed braces is recommended by a physician.

According to S. H. Camp and Company, these garments are available in corset departments of selected department stores, certain corset shops, and reliable surgical supply houses. The garments are sold to patients on the prescription of a physician, and his directions are followed when the fit is made. The fitters are trained by S. H. Camp and Company in its own school under the direction of a physician. These fitters are instructed to follow implicitly the directions of the physician when fitting the garment. They are warned against attempting

to diagnose the condition, and, whenever there appears to be an indication of a misfit of the garment, the patient is referred back to the physician in charge.

S H Camp and Company has informed the Council that it has never paid commissions or rebated any percentage of the selling price to physicians on any of its merchandise, and assures the Council that it will not do so in the future.

These belts and supports have been investigated in clinics acceptable to the Council on Physical Therapy and have been found to meet satisfactorily the therapeutic claims made for them.

The Council therefore voted to include these Camp Supports in its list of accepted devices.

FISCHER SHORT WAVE HIGH FREQUENCY APPARATUS ACCEPTABLE

Manufacturer H G Fischer and Company, Inc., Chicago

This unit is recommended for medical diathermy as used for producing heat within the body tissues.

The apparatus is mounted in a wooden cabinet on a chassis of open frame construction containing all parts and instruments readily removable as a unit from the cabinet for repairs and inspection. The circuit is of a well known oscillating type with the addition of the rectifying unit. All high voltage and high frequency currents are well insulated from the wooden chassis with the aid of stand-off insulators and bakelite washers. Two vacuum tubes and two rectifying mercury tubes are employed.

Protection is afforded to the tubes against overload by the circuit breaker, which automatically limits the currents whenever the current through the tube reaches the dangerous point. The circuit breaker opens and the current limiting resistance keeps the current through the tube within a safe value. The meter used is of the thermocouple type having two scales—a high and a low reading. This meter does not record the current passing through the patient but indicates when the apparatus is in electrical resonance.

After several hours of operation, the maximum transformer temperature read 176 F, which is within the limits of safety. The frequency of the energy is about 127 megacycles per second, which corresponds to a wavelength of about 24 meters.

The input power was found to be 627 watts (average of five tests). So far as is known, there is no reliable or acceptable method of measuring the power output of short wave diathermy machines.

The machine was tested in a clinic acceptable to the Council for a period of two months, and the investigator reported that the unit supplied sufficient energy to heat the body tissues whenever such treatment was indicated. The unit was not used for hyperpyrexia treatments. It was tried out for tissue cutting and it appeared to be satisfactory in this respect.

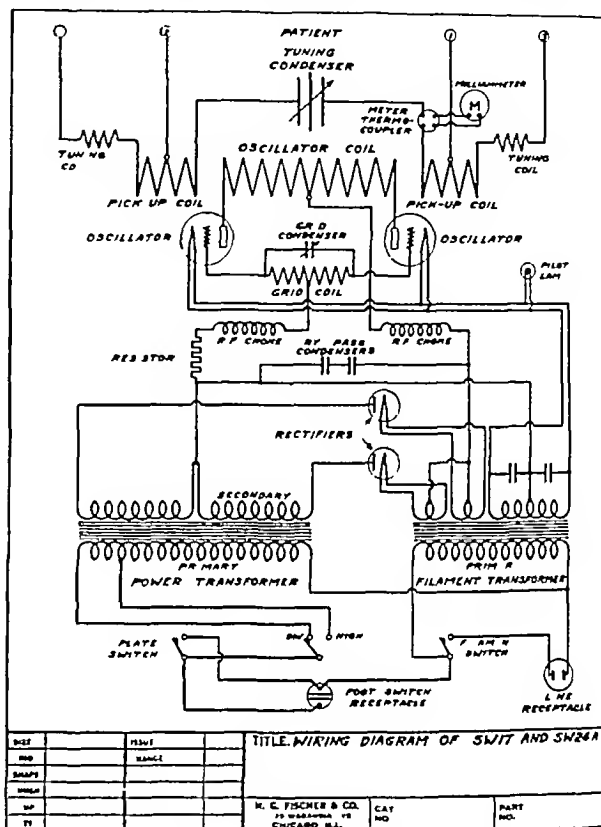

Fischer Short Wave High Frequency Apparatus

In a series of observations on anesthetized dogs, the heating effects of the Fischer Short Wave Machine were investigated. The average of twelve tests showed that there was a temperature rise in the kidney, rectum, liver and spleen. However, the temperature rise was not as great as that obtained by diathermy with the same size electrodes. In this series of tests the unit operated at full load, and the electrode pads were applied on each side of the thorax.

The tissue heating effect in the human thigh was also investigated. Thermocouples were introduced into the subcutaneous deep lying tissue (quadriceps extensor). After twenty min-

utes' treatment operating at the patient's tolerance and using the electrode pads, the temperature rise was observed to be less than that for diathermy. However, when cuff electrodes were used, that is, long electrodes wrapped around the thigh, the temperature rise in the deep lying tissues was above that obtained by diathermy (average of three tests).

This machine will produce a substantial heating effect in body tissues, provided cuff electrodes are employed, but the

Schematic diagram of circuit.

heating effects produced by the electrode pads are less than that of diathermy. Burns may be produced by this machine, but, with ordinary care, they may be avoided. Their likelihood to occur is much less than that of diathermy.

In view of the foregoing report, the Council on Physical Therapy voted to include the Fischer Short Wave High Frequency Apparatus in its list of accepted apparatus.

THERMAT SELF-HEATING HEAT PAD ACCEPTABLE

Manufacturer Bauer and Black, 2500 South Dearborn Street, Chicago

This pad may be used as a substitute for a hot water bottle. Heating is accomplished by means of the chemical reaction. The chemical mixture consists of finely divided iron, sodium chloride, and manganese dioxide. It contains 84 per cent iron, 10 per cent manganese dioxide and 6 per cent sodium chloride. When a couple of teaspoonfuls of water are added, a chemical action takes place during which heat is evolved. The receptacle consists of a flexible rubber material and the heat mixture proper is contained in a canvas bag. The size of it is approximately 12 by 10 inches. The weight is 18 ounces. When the patient is through with the bag, the cover may be removed and the pad will cool off rapidly. After the unit is cooled, it is again ready for use. It has a life of from eighty to 125 hours. The estimated cost of operating the Thermat is about one-third cent per hour of actual use.

The Council on Physical Therapy voted to include the Thermat Self-Heating Pad in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTIONS WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

PYRETHRUM OINTMENT—An ointment containing an extract from powdered pyrethrum flowers (*Chrysanthemum cinerariaefolium*). The extract is obtained by treating powdered pyrethrum flowers with a hydrocarbon oil of the kerosene type, this extract is then incorporated into an ointment base composed of hydrous wool fat, petrolatum and paraffin. The finished ointment contains 27 per cent of the active extract (representing 0.75 per cent of pyrethrins I and II) and 73 per cent of ointment base.

Actions and Uses—Pyrethrum ointment-Upsher Smith has been shown to be an effective agent in the treatment of scabies. Based on the (as yet unpublished) investigation of Sweitzer and Tedder the claim is made that the ointment penetrates the burrows and kills both the mites and the eggs and that except in rare instances it does not produce dermatitis with resultant exfoliation. Sweitzer and Tedder reported four cases of allergic sensitivity to the active substance in a series of 618 patients treated.

Dosage—The ointment is applied to the entire body following a thorough cleansing with soap and water. Further applications are made on at least three or four successive days. In most cases it is necessary to continue the treatment for a period of from five to seven days, and in obstinate cases the use of the ointment may be required for a longer time. The ointment should not be used on patients who are sensitive to pyrethrum flowers.

Manufactured by the Upsher Smith Company Minneapolis No U S patent or trademark.

Pyrethrum ointment is an unctuous yellowish green mass. Place 5 Gm. of pyrethrum ointment in a suitable flask, add 25 cc. of half normal potassium hydroxide alcoholic solution and an equal volume of water and heat the mixture under a reflux condenser for five minutes. The alcohol is removed by evaporation the mixture cooled and allowed to separate. Remove the liquid by decantation add sufficient barium chloride solution, thoroughly mix and allow to separate. To the mixture add 1 cc. of sulphuric acid to remove the excess of barium salt. To about 5 cc. of the filtrate add an equal volume of mercuric sulphate solution an immediate pink color develops which deepens on standing finally changing to a green coloration with the development of a turbidity or a precipitate (*monocarboxylic acid*). Determine the pyrethrin content by the procedure (with slight modification) described by Seil in Soap in May 1934 the combined pyrethrin content (pyrethrins I and II) is not less than 0.75 per cent nor more than 1 per cent.

ANAEROBIC ANTITOXIN (See New and Nonofficial Remedies, 1935, p 366)

U S Standard Products Co, Woodworth, Wis

Polynaerobic Antitoxin (Tetanus Gas Gangrene) Refined and Concentrated (U S S P Co)—An antitoxic serum prepared by immunizing horses with the toxins of *B. tetani*, *B. perfringens* (*B. welchii*) and vibrios septique. When tests of trial bleedings indicate that the potency is sufficiently high the horses are bled into anticoagulant and the plasma concentrated and refined by methods according to the Park Banzhaf process. The unit values of the concentrates are determined according to the methods described by the National Institute of Health. It is marketed in packages of one syringe one prophylactic dose containing vibrios septique antitoxin 2,000 units, tetanus antitoxin 1,500 units and *B. perfringens* (*B. welchii*) antitoxin 1,000 units.

Dosage For prophylaxis The contents of one syringe injected subcutaneously or intramuscularly

AMINOACETIC ACID (See THE JOURNAL, April 6, 1935, p 1241)

Aminoacetic Acid-Merck—A brand of aminoacetic acid N N R.

Manufactured by Merck & Co Inc. Rahway N J No U S patent or trademark.

ALLERGENIC EXTRACTS-LEDERLE (See New and Nonofficial Remedies 1935, page 28)

The following dosage form has been accepted

House Dust (New York Apartment House) Allergic Extract Lederle Marketed in vials containing respectively 6 cc of undiluted and diluted 1:10 extract of New York apartment house dust.

The product is prepared in the following manner vacuum cleaner collections from New York apartment houses are dried sifted and extracted with toluene alcohol and ether. The dry powder is then extracted under toluene with the buffered solution. After dialysis the extract is concentrated and sterilized.

COD LIVER OIL (See New and Nonofficial Remedies, 1935, p 292)

Abbott's Cod Liver Oil—It has a vitamin A potency of not less than 1,500 units (U S P X-Revised, 1934) per gram and a vitamin D potency of not less than 100 units (U S P X-Revised, 1934) per gram.

Manufactured by the Abbott Laboratories North Chicago Ill No U S patent or trademark.

Abbott's cod liver oil complies with the U S P X Revised 1934 standards for cod liver oil. In addition it is required to have a vitamin A potency of not less than 1,500 units per gram and a vitamin D potency of not less than 100 units per gram as described by the method of the U S P X Revised 1934.

ANTIPNEUMOCOCCIC SERUM (See New and Nonofficial Remedies 1935, p 377)

Parke, Davis & Co, Detroit.

Antipneumococcic Serum (Felton) Types I and II Refined and Concentrated—Prepared by immunizing horses against highly virulent but dead cultures of *Diplococcus pneumoniae* isolated from lobar pneumonia. The product is refined and concentrated by a method devised by Dr L. D. Felton and contains antibacterial properties against *Diplococcus pneumoniae* types I and II. Marketed in packages of one vial with syringe attachment containing 10,000 Felton units each of types I and II pneumococcus antihodies with a vial of normal horse serum diluted 1:10 for reaction test and in packages of one vial with syringe attachment containing 20,000 Felton units each of types I and II pneumococcus antihodies with a vial of normal horse serum diluted 1:10 for reaction test.

Dosage—From 10,000 to 20,000 Felton units repeated at intervals of four to six hours during the first twenty-four hours intravenously.

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1935, p 397)

E. R. Squibb & Sons, New York

Refined Diphtheria Toxoid Alum Precipitated Squibb—Also marketed in packages of one 1 cc. vial, in packages of ten 1 cc. vials and in packages of one 10 cc. vial representing one, ten and ten immunizing doses respectively.

DEXTROSE (See New and Nonofficial Remedies, 1935, p 280)

The Sterisol Ampoule Corporation, Long Island City, N Y

Sterisol Ampoule Dextrose 5% in Physiological Solution of Sodium Chloride A solution containing in each 100 cc. 5 Gm of anhydrous dextrose and 0.85 Gm of sodium chloride. Supplied in ampoules containing 250, 500 and 1,000 cc.

DEXTROSE (See New and Nonofficial Remedies, 1935, p 280)

The National Drug Company, Philadelphia

Ampul Solution of Dextrose 10 Gm 20 cc Each ampule contains dextrose C P anhydrous 10 Gm in distilled water to make 20 cc.

Ampul Solution of Dextrose 25 Gm, 50 cc Each ampule contains dextrose C P anhydrous 25 Gm. in distilled water to make 50 cc.

Ampul Vial Solution of Dextrose 25 Gm 50 cc Each ampule-vial contains dextrose C P anhydrous 25 Gm in distilled water to make 50 cc.

Ampul Vial Solution of Dextrose 50 Gm 100 cc Each ampule-vial contains dextrose C P anhydrous 50 Gm in distilled water to make 100 cc.

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH Secretary

"DYNO" NOT ACCEPTABLE AS A PROPRIETARY NAME FOR DEXTROSE

Some years ago the Council had before it the consideration of the brand of dextrose-U S P marketed by the Corn Products Refining Company under the proprietary name "Cerelease." The product had been presented to the Committee on Foods. When the Committee on Foods was established by the Board of Trustees of the Association as a separate entity from the Council on Pharmacy and Chemistry, it was stipulated that, in the acceptance by the Committee on Foods of products used both as foods and in the treatment of disease, the name must meet the requirements of the rules of the Council. The Council ruled that the proprietary name Cerelease could not be recognized as a name for the well known substance dextrose. The Committee on Foods concurred and the firm was informed of this decision.

Later, the Corn Products Refining Company submitted to the Committee on Foods its dextrose under the name "Dyno" and the question was again referred back to the Council. The Council reaffirmed its stand concerning the use of a proprietary

name for dextrose, pointing out that the firm could make a very appropriate adaptation of the brand name "Argo," which it uses for corn starch, to apply to its dextrose, for example, "Argo Dextrose Anhydrous" and "Argo dextrose, Hydrated." It was pointed out that such names would not conflict with the rules of the Council and would be acceptable to the Committee on Foods.

In the letter of the Corn Products Refining Company requesting the Council's consideration of this question, was included the text of a proposed label statement:

One of the panels of the proposed label was to contain the following:

D Y N O
Reg. U. S. Pat. Off.
Pure Dextrose
A pure refined table sugar
Derived from Corn

The other panels of the proposed label contain claims in regard to the uses of dextrose as a food. The Council held certain of these claims to be distinctly misleading in suggesting that dextrose is superior as a food to cane sugar. That may be true in special cases which would come under the heading of therapeutics, but in normal individuals the Council would be inclined to doubt any claim of material superiority, except as regards the degree of sweetness.

When the firm was informed of the Council's consideration of its request it replied that there was no intention to suggest that dextrose is superior as a food to cane sugar. However, a careful reading of the text submitted by the firm shows that this implication may be taken.

The firm made no agreement to discontinue the use of the proprietary name Dyno and the Council therefore authorized publication of this explanatory statement.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS
RAYMOND HERTWIG, Secretary

NOT ACCEPTABLE

GRAIN-LAX THE PREDIGESTED COMPLETE FOOD

William C. Arthurs, Glendora, Calif., submitted to the Committee on Foods a bread prepared from water, honey, whole wheat, rolled oats, potato flour, dry milk, bran, vegetable shortening, baking powder and salt, called "Grain-Lax The Predigested Complete Food."

Manufacture—The ingredients in formula proportions are mixed and baked for four hours in air tight containers in a steam chamber at temperatures ranging from 260 to 230 C.

Discussion of Label—The label states:

The Predigested Complete Food. A combination of Grain products. Mineral Salts. Milk and Honey. A tissue builder and NATURAL APERIENT. Improvement in health will be noticed after two weeks consistent use—Especially good for growing children.

The nutritional values of this bread are essentially those of whole grain cereals, supplemented by a small amount of milk. The indigestible fibrous content is sufficient to aid in counteracting constipation due to insufficient bulk.

The product is not predigested; it must be digested just as are usual bakery goods before the nutrient content is available to the body. This is not a complete food as claimed. A number of essentials for adequate nutrition are absent and others are not present in adequate quantity for good nutrition. The declaration of ingredients is incomplete, potato flour, bran, shortening and baking powder are not listed. Mineral salts as such are not added as stated. Descriptive statements of ingredients of compounded foods, to be correctly informative, should name all ingredients in the order of decreasing proportions, thereby giving more prominence to materials in major quantity. The name 'Grain-Lax' and the claim 'Natural Aperient' acclaim the product for counteracting constipation

no matter what the cause. Constipation, however, may be due to many causes not correctable by this bread, which essentially is an aid for counteracting constipation due only to insufficient bulk in the diet. The consumer should be advised accordingly. The product is not 'especially good for growing children.' The claim 'Improvement in health will be noticed after two weeks consistent use,' because of vagueness, is grossly misleading. Many conditions of ill health will not be improved by this bread, and others may be seriously aggravated by a coarse food of this character. Such claims promote self diagnosis and self treatment, practices dangerous to health. Those in ill health should be under the care of a competent physician. Prescribing through advertising is inimical to public welfare. Grain-Lax, therefore, will not be listed among the Committee's accepted foods.

NOT ACCEPTABLE

JOHNSON'S MILCO-MALT

The Canada's Pride Products Company, Inc., New York City, submitted to the Committee on Foods a powdered mixture of sucrose, cocoa, malted milk and salt, flavored with vanillin, called 'Johnson's Milco-Malt.'

Analysis (submitted by manufacturer) —

	per cent
Moisture	20
Ash	19
Fat (ether extract)	36
Protein (noncaffeine and nontheobromine N × 6.25)	110
Nitrogen	18
Crude fiber	30
Carbohydrates other than crude fiber (by difference)	78.1
Theobromine	0.31
Caffeine	0.06

Discussion of Name Label and Advertising—The label states:

A blend of finest grade of pure malted milk, cocoa and cane sugar. Is composed of only health giving ingredients. Boiling destroys the health giving ingredients. Some claims from the submitted advertising follow: 'Milco-Malt the builder of strong bodies, keen minds, steady nerves—an essential in every day life. Many victors, baseball players, prize fighters, business leaders, successful men and women now keep well and healthy by drinking Milco-Malt. This invigorating food-drink restores energy and builds up vitality. Makes little bodies strong and sturdy. Grownups drink Milco-Malt regularly to restore energy and vitality. Combined with milk this single drink gives you many health benefits. That's health news too for Milco-Malt builds sturdy bodies from teeth to toes, generating body warmth, energy, strength, and weight. Milco-Malt is a balanced food, just chock full of fats, minerals, proteins, carbohydrates and vitamins. Milco-Malt keeps children alert in school, active in play and restful in sleep.'

The name 'Milco-Malt' phonetically equivalent to malted milk, suggests the product is a beverage base which with water produces essentially a malted milk and thereby creates a false impression of the nature and nutritional value of the product. The milk solids content of Milco-Malt is insufficient to justify "Milco" as a part of the name. The statement of composition on the label does not correct the misleading character of the name. The descriptive statement "blend of pure malted milk, cocoa and cane sugar" overemphasizes the malted milk content by mentioning it first. Cane sugar is the predominant ingredient. Descriptive statements for food should list ingredients in the order of decreasing proportions, thereby giving first place or more prominence to the ingredients occurring in major quantity.

Milco-Malt contains no 'health giving' ingredients, no constituents that will build keen minds, sturdy nerves, enable persons to keep well and healthy, or 'restore energy and vitality.' No foods can give health or energy and vitality. These conditions depend on many factors not provided even by the complete diet. It is not 'a balanced food' nor is it chock-full of fats, minerals, proteins and vitamins.

The name is inappropriate and the advertising misleading and misinformative. Advertising falsely presenting products compounded from ordinary foods such as milk, cocoa and sugar, as health foods with mythical values for giving or restoring health and vitality, is against the best interests of the public and the food industry and is a serious handicap to manufacturers and advertising agencies earnestly attempting to serve the public honestly. Milco-Malt therefore cannot be listed among the Committee's accepted foods.

NOT ACCEPTABLE

(1) SEAKIST SIEVED CEREAL

(2) SEAKIST SIEVED VEGETABLE SOUP

The Nielsen Corporation, Limited, Oakland, Calif., submitted to the Committee on Foods (1) a sieved whole wheat flour product cooked in milk and water called "Seakist Sieved Cereal" and (2) a sieved vegetable soup containing water, tomato puree, carrots, celery, cabbage, barley flour, butter, whole wheat flour, sucrose, yeast extract, onions, and salt called "Seakist Sieved Vegetable Soup"

Discussion of Names—The names "Seakist Sieved Cereal" and "Seakist Sieved Vegetable Soup" incompletely and inappropriately define and describe the products. Milk is an undeclared ingredient of the sieved cereal, barley and whole wheat flours and yeast extract undeclared components of the vegetable soup. These are not expected ingredients in products with the respective names. The public is entitled to know the ingredients of foods it purchases, food names, if at all descriptive, should correctly define the nature and composition of the food articles. The food industry should exercise care in naming and labeling foods that the consumer may be correctly informed.

The company was advised of the recommendations of the Committee but is not willing to make the recommended changes. These products therefore will not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

- (a) MELVERN VANILLA ICE CREAM
- (b) MELVERN CHOCOLATE FLAVORED ICE CREAM
- (c) MELVERN STRAWBERRY ICE CREAM
- (d) MELVERN PEACH ICE CREAM
- (e) MELVERN PECAN KRUNCH ICE CREAM
- (f) MELVERN BUTTERED PECAN ICE CREAM
- (g) MELVERN BLACK WALNUT ICE CREAM
- (h) MELVERN PINEAPPLE ICE CREAM
- (i) MELVERN ORANGE-PINEAPPLE ICE CREAM
- (j) MELVERN CHERRY CUSTARD ICE CREAM
- (k) MELVERN PISTACHIO ICE CREAM (ADDED ALMOND FLAVOR)
- (l) MELVERN FRENCH VANILLA ICE CREAM
- (m) MELVERN LEMON CUSTARD ICE CREAM

Manufacturer—Melvern Dairies, Inc., Washington, D. C.

Description—(a) Prepared from a pasteurized homogenized mixture of condensed milk cream (40 per cent) water, sucrose, gelatin vanilla extract and United States Department of Agriculture certified color.

- (b) Same as (a) with added chocolate and cocoa
- (c) Same as (a) with added strawberries sucrose and certified color
- (d) Same as (a) with added peaches and certified color
- (e) Same as (a) with added pecans
- (f) Same as (a) with added buttered pecans
- (g) Same as (a) with added black walnut salad and caramel
- (h) Same as (a) with added canned crushed pineapple
- (i) Same as (a) with added crushed orange and pineapple and certified color
- (j) Same as (a) with added cherries, maraschino cherries, egg custard prepared from egg yolks sugar cream (40 per cent) whole condensed milk and water and certified color

(k) Same as (a) with added pistachio nuts, ground almonds, almond extract and certified color

(l) Same as (a) with added egg yolk, and certified color

(m) Same as (a) with added egg yolk, lemon juice, lemon oil and certified color

Manufacture—Sugar and gelatin are added to the cream (40 per cent), condensed milk and water, which have previously been heated to 43 C. The combined ingredients are pasteurized by the holding method at 68 C. for thirty minutes, homogenized, cooled to 4 C., allowed to stand twelve hours and frozen for twelve minutes. The special flavors, fruits and other ingredients are added during the freezing process. The frozen ice cream is packed in cartons, in waxed paper cups, and in nonreturnable paper cans the lids of which carry the name of the product and date of manufacture. The ice cream in containers is hardened at -29 C. The ice cream for cut brick form is run directly from the freezer into pans and when hard is removed, placed on white parchment paper, cut into slices and each slice individually wrapped and inserted into cartons, which are sealed with gummed tape bearing the appropriate name. Four of these packages are sealed in a paper bag, the seal bearing the name of the product and date of manufacture. The various types of ice cream are prepared from the basic ice cream mix by addition of appropriate flavors, fruits or nuts in definite proportions.

CELLU GRAPEFRUIT PACKED IN WATER
WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Florida Citrus Exchange, Tampa Fla.

Description—Canned cooked Florida grapefruit packed in water without added sugar or salt.

Manufacture—Grapefruit picked at the proper stage of ripeness is washed polished and graded according to size. Cannery size fruit is peeled by hand and the rag removed, the fruit is separated into sections, the membrane is removed, and the fruit is placed in cans covered with water and heated. The cans are sealed, processed and cooled.

Analysis (submitted by distributor) —

	per cent

FAT ABSORPTION

The manner in which fats are absorbed from the alimentary canal has long been a controversial subject.¹ Although the evidence is clear that neutral fat is hydrolyzed by the lipases of the alimentary tract prior to absorption, there is lack of agreement concerning the nature of the process by which the water-insoluble fatty acids are brought into solution and transported across the intestinal wall. Pflüger believed that the insoluble fatty acids liberated during fat digestion combined with the alkali of the pancreatic juice to form soaps. The latter, by virtue of their solubility in water, could readily diffuse into the epithelium. Recent investigations of the reaction of the intestinal contents have thrown some doubt on the assumption that these materials are generally alkaline. It has, in fact, been demonstrated that an alkaline reaction is seldom, if ever, found in the small intestine. These observations increase the significance of the role of the bile in fat absorption and have resulted in detailed studies of the mechanism by which this fluid facilitates the passage of fat through the intestinal wall.

The general importance of the bile in fat absorption has long been known. In addition to augmenting the activity of the hydrolytic lipases, the main function of bile apparently is to increase the solubility of the fatty acids and soaps in the intestine and thus aid their transport through the absorbing cells. The exact manner in which bile functions in this capacity has never been adequately elucidated. Within recent years, however, the extensive investigations of Verzar and his colleagues at the University of Basel, Switzerland, have greatly clarified the important role of bile in the absorption of fats. In addition to the well known ability of the bile acids to emulsify fats by virtue of their surface tension-lowering properties, it has been demonstrated that these bile acids appear capable of bringing a considerable amount of insoluble fatty acids into solution in water. This property of certain substances to bring other

insoluble materials into solution in water is called hydrotropism, a term first suggested by Neuberg. The increase in solubility effected by hydrotropic substances may be of considerable magnitude. Despite this augmented solubility, however, the question why less bile acid is required for fat absorption in the intestine than is necessary in vitro still remains to be answered. It appears likely that the bile acids must act locally on the permeability of the intestinal mucous membrane. Following this suggestion, Verzar points out that it is therefore unnecessary for the bile acids to dissolve all the fatty acid at a given instance. Instead, the bile acids may be adsorbed on the surface of the epithelial cells of the intestinal mucous membrane and in that position can repeatedly conduct new quantities of fatty acids in water-soluble form through the surface of the epithelium. This idea gains support from the well known fact that the fat present in the interior of the epithelial cells is neutral fat, the bile acid-fatty acid complex must therefore have been split in the cell. The liberated bile acid, as a strongly surface-active substance, could easily be adsorbed on the cell surface, especially on to the outer finely striated border of the cells. There it might repeatedly dissolve fatty acids and transport them through the membrane. It is recognized that conclusive experimental evidence of the accuracy of Verzar's conception is difficult to obtain, but this newer hypothesis does afford an interesting graphic account of the manner in which bile exerts its influence on fat absorption.

The rate of fat absorption is often mentioned in clinical literature as a valuable aid in the appraisal of the normal functioning of the liver. The estimation of the degree of alimentary lipemia is generally taken as an index of the rate of fat absorption. A recent study of this type has been reported from the Tulane University of Louisiana School of Medicine.² Fat absorption curves of normal men and of patients with disease of the liver were obtained by following the changes in total lipids of the serum subsequent to the ingestion of 100 Gm of cottonseed oil. Patients with definite disease of the liver showed an absorption curve distinctly different from the normal and denoting a diminished and delayed absorption of ingested fat. This altered absorption curve, based on blood lipid values, is deemed by the investigators sufficiently characteristic and different to be of aid in determining the status of the function of the liver. Although sporadic reports of this type support the use of this procedure in diagnosing liver function, the results of determinations of the rate of fat absorption from studies of lipemia should be interpreted with caution. The quantity of fat in the blood at a given time is subject to the influence of a number of factors. The rate of uptake from the alimentary tract and the rate of deposition of the absorbed material in the body cells are important regulators of the level

¹ Bloor, W. R. *Physiol. Rev.* 2:92 (Jan.) 1922. Verzar, F. *Nutrition Abstr. & Rev.* 2:441 (Oct.) 1933.

² Sullivan, Maurice, and Fershtand, J. A. B. *Fat Absorption Arch. Int. Med.* 65:834 (May) 1935.

of blood lipid. It should be remembered that lipemia occurs in diabetes as well as in starvation and does not, on the other hand, develop in cases of cirrhosis of the pancreas or carcinomas affecting other abdominal organs. These few instances of altered blood lipid levels, unrelated directly to liver functioning, suffice to emphasize the limited importance that should be attached to fat absorption, or alimentary lipemia, as a diagnostic measure of hepatic condition.

EFFECTS OF EMOTIONAL EXCITEMENT

The classic and recurring tale of some frail individual who under the stress of excitement lifted and removed a trunk or other heavy object which later three strong men could scarcely raise has been too often verified to discard as fiction. Such an episode must be viewed as one effect of strong emotional disturbance. Emotion as a state that can produce extraordinary psychologic as well as physical reactions has long interested clinicians, psychologists and physiologists.

It has been regarded¹ as a complex having four aspects: (1) behavioristic—the facial expression and observable action, (2) physiologic—vascular, secretory, neuromuscular and other changes, (3) introspective—the conscious attributes, and (4) psychopathologic—the pathologic disturbances of emotional life. Whether it is possible to separate these factors in a significant manner is still a matter of speculation, but Morris² has adopted a scheme of comparing the pulse, blood pressure and blood sugar under a state of excitement with that of the same individual when calm. The psychologic literature, Morris states, contains numerous studies of the pulse, blood pressure and other physiologic variables in individuals during and following the application of a standardized stimulus intended to produce an emotional state. There is a sufficiently large body of data of this type, usually well analyzed statistically, the only obvious but important deterrent to an acceptance of these conclusions being the question as to whether the stimulus, artificial as it must be, is in any way comparable to the stimuli received by people under the ordinary stress of life.

In determining the presence of emotional excitement, four criteria were used by Morris. The first was the knowledge of the situation by the observer, the second the subject's introspective report, the third the observation of facial expression and actions, and finally such observable bodily changes as tremor, flushing or pallor, perspiration or lacrimation. Knowledge of the situation by the observer and at least one of the other criteria were considered necessary to establish the presence of emotional excitement.

The pulse rate was counted by palpation of the radial artery in most instances. The blood pressure was determined in all cases by the use of a mercury sphygmomanometer. The blood sugar was estimated by a combination of the method given by Somogyi³ and the colorimetric method of Benedict.⁴

Twenty-six subjects were studied during a state of mild excitement and during a state of calm. When tabulated there was an average rise of 22.1 mm in systolic pressure, 11.8 in diastolic pressure and 14.3 in pulse rate during the period of excitement. There was, however, considerable individual variation in each of these physiologic variants.

In another series of eight showing prolonged emotional excitement, the blood sugar levels were noted especially. Control values were obtained in five while in a state of calm. The rise in the blood sugar during excitement were respectively 20, 25, 30, 42 and in one case 149 mg. One case of manic-depressive psychosis was included. While excited, this individual had a blood sugar of 79 mg, a blood pressure of 120/80 and a pulse rate of 104, when calm, 78 mg, 110/78 and 86.

The fact that certain physiologic variations under emotional stress verge on the pathologic does not come as a surprise. Among other indications of possible significance it adds point to the common observation that the pulse and blood pressure recorded on patients on their first visit to a physician are frequently not a satisfactory index of the patient's norm.

THE BACTERICIDAL AND BACTERIOSTATIC EFFECTS OF MERCUROCHROME

The comparative evaluation of antiseptics involves many difficulties. Numerous procedures have been devised in the hope of avoiding at least some of the sources of error that arise from transfer to clinical usage of results obtained in test tube experiments. Adequate standard methods have not yet been developed, consequently studies in this field by different workers are rarely comparable. This has led to great confusion and much controversy.

Elsewhere in this issue is an article by Justina H. Hill¹ of the Brady Urological Institute (whence mercurochrome originated) concerning the action of mercurochrome in comparison with some other preparations on normal human skin and in infected wounds in animals. Miss Hill presents an extensive series of experiments on the comparative bactericidal and bacteriostatic effects of 2 per cent aqueous and 2 per cent acetone-alcohol-aqueous solutions of mercurochrome.

¹ Hill Justina H. The Action of Mercurochrome and Other Drugs on Normal Human Skin and in Infected Wounds. *this issue* p. 100.

and of tincture of iodine applied to normal human skin. She concludes from her investigations that both aqueous and acetone-alcohol-aqueous solutions of mercurochrome are bactericidal and bacteriostatic when applied to human skin but that the acetone-alcohol-aqueous solution is superior for this purpose to the aqueous preparation. Miss Hill found further that the acetone-alcohol-aqueous solution, under the conditions of her tests, exerted greater bacteriostatic effects than 7 per cent tincture of iodine. Comparative studies on the effects of the two preparations of mercurochrome 7 per cent tincture of iodine, tincture of merthiolate, aqueous solution of merthiolate, tincture of metaphen, neutral acriflavine in salt solution, and hexylresorcinol solution, on subcutaneous wounds inoculated with *Staphylococcus aureus*, indicated that the 2 per cent aqueous solution of mercurochrome was superior to all the others in reducing the number of organisms and in producing the least interference with phagocytosis.

In order to obtain a reasonably clear picture of the clinical effectiveness of antiseptics, it is necessary to analyze the data obtained with various methods of evaluation and to correlate these with the results of actual clinical application. Only a few of the many investigations can be considered here. Simmons,² for instance, found mercurochrome to be decidedly inferior to tincture of iodine in the disinfection of wounds. Miss Hill has confirmed these observations though she considers that the time intervals employed by Simmons were too short. With intervals of twenty-four hours, none of the antiseptics employed by Miss Hill were found to sterilize wounds infected with *Staphylococcus aureus*. However, it must be noted that her comparison of the effectiveness of the different antiseptics was based largely on bacterial counts from swabs inserted into the wounds, apparently without consideration as to whether the visible organisms were alive or dead. Also, variations in the amount of exudate produced under the influence of the different antiseptics, which undoubtedly would affect the bacterial count, appear not to have been evaluated.

Scott and Birkhaug³ showed that tincture of metaphen and tincture of iodine were both superior to acetone-alcohol-aqueous solution of mercurochrome for skin sterilization, tincture of metaphen being the most effective of the three. Birkhaug⁴ found phenylmercuric nitrate, metaphen and tincture of iodine all to be much superior to mercurochrome for skin disinfection, phenylmercuric nitrate being the best for this purpose. In test tube experiments with six different organisms, this investigator found that phenylmercuric nitrate had 434 times, metaphen 310 times, merthiolate

271 times, mercuric chloride 76 times and hexylresorcinol 45 times the germicidal potency of mercurochrome.⁵

Thus it appears from these and other studies, in particular the investigation by von Oettingen,⁶ that most workers have found mercurochrome to be a relatively weak antiseptic. This is not contradicted by the data presented by Miss Hill, the results of her investigations, so far as they appear to be fully valid, supplement rather than conflict with those of the other studies. It must be appreciated that the alleged superiority of any antiseptic, and, in this case, of mercurochrome, is dependent on the conditions under which this superiority was demonstrated. Mercurochrome has been used clinically for a sufficient time so that its relative effectiveness in actual practice is now fairly well known. The consensus appears to be that mercurochrome is a moderately active antiseptic, it is relatively nonirritant and it has a certain definite but quite limited usefulness in the prevention and treatment of certain infections.

Current Comment

DINITROPHENOL AND CATARACT

In this issue of *THE JOURNAL* appear reports¹ of several cases in which cataract seems to have occurred almost in the form of a malignant development in persons who had been taking dinitrophenol for long periods of time. The coincidence is of interest regardless of whether or not it may be established that the disturbance arose because of the dinitrophenol or because of some other undetected cause. It should of course, be borne in mind that dinitrophenol has not been standardized chemically. The possible occurrence of toxic contaminants in preparations of dinitrophenol must be considered. The possibility also exists that the cataracts may have resulted from associated malnutrition and an unbalanced diet, which are in many instances a part of the program of those who attempt rapid reduction of weight by the use of dinitrophenol or other methods. *THE JOURNAL* has warned its readers repeatedly against the dangers of uncontrolled use of new preparations of this type. The incident here recited serves as a further warning against use of these products until the actual merits and dangers may be more definitely determined. The report of the Council on Pharmacy and Chemistry rejecting dinitrophenol² for inclusion in New and Nonofficial Remedies, published last week, further emphasizes the hazards of the use of dinitrophenol and related substances.

¹ These figures of course refer to the substances themselves and not to the relatively dilute solutions in which they are marketed.

A 'Bowler Day' was held in his honor, May 4, marked by athletic events and a banquet attended by many athletic stars he had developed during his career

NEW MEXICO

Personal—Dr. Frank W. Parker Jr., San Bernardino Calif., has been appointed district health officer in charge of Grant Luna and Hidalgo counties, with offices in Silver City—Dr. Elroy F. McIntyre, Santa Fe, was elected president of the New Mexico Public Health Association

Vital Statistics—The death rate in New Mexico for 1934 was 134 per thousand of population, compared with 132 in 1933, according to the *New Mexico Health Officer*. Infant mortality was reduced from 1334 per thousand live births to 1226. Accidental deaths increased in 1934 to 383, from 313 in 1933, automobile accidents were responsible for 131 deaths in 1934 as compared with 101 in 1933. A tabulation of deaths from diarrhea and enteritis in children under 2 years of age during the past five years showed an average rate of 80.8 per hundred thousand of population. One county, however, reported only one death from this cause in the five years.

NEW YORK

Fifty Years of Hospital Service—Dr Lawrence G. Hanley, Buffalo, was the guest of honor at a dinner, May 23, celebrating his fiftieth anniversary on the surgical staff of the Buffalo Hospital of the Sisters of Charity, with the sisters as hosts and Dr Pierce J. Candee as toastmaster. On behalf of the medical staff Dr John T. Donovan presented a gold watch to Dr Hanley, and for the nurse alumnae of the hospital Dr Thomas J. Walsh presented a traveling bag.

Personal—Drs Lucius H. Smith, Palmyra, and Myron E. Carmer, Lyons, were guests of honor at a meeting of the Wayne County Medical Society, Lyons, June 4, marking their completion of fifty years of practice. Dr Smith is a graduate of Syracuse University School of Medicine and Dr Carmer of the University of Vermont School of Medicine.—Dr Hans P. Hanson, formerly in charge of veterans' facilities at St. Cloud, Minn., has been appointed head of the Veterans' Administration Facility at Canandaigua.

New York City

Street Named for Madame Curie—A section of the highway along the East River from Sixty-Third to Seventy-Ninth Street, hitherto known as Exterior Street, was renamed Marie Curie Avenue at a ceremony, June 9, at which Mayor La Guardia made the dedicatory speech. Among other speakers who eulogized the late Madame Curie were Dr James Ewing of Memorial Hospital and Dr Anthony M. Sawicki of the Brooklyn Curie committee. Mrs. William Brown Meloney presided.

Assembly of Data by Relief Workers—Emergency relief workers are assembling data on health subjects including the trapping of rats in a campaign to eliminate them as possible carriers of typhus fever, investigation of the chemicals used in beauty shops, investigation of various stores to determine whether potentially harmful drugs and medical preparations are sold in places other than registered pharmacies, study of the mental and emotional development of children, a tuberculosis survey, and an investigation to find children not immunized against diphtheria.

Dinner to Dr Linder—The board of directors and the medical staff of the Jewish Hospital of Brooklyn gave a dinner at the Waldorf Astoria, June 9, in honor of Dr William Linder, who was recently elected dean of surgery of the hospital. Speakers at the dinner were Joseph J. Baker, president of the hospital, Edward Lazansky, vice president, Irwin Steingut, director, and Drs. Meyer A. Rabinowitz, president of the medical board, and Leo S. Schwartz, representing the alumni and medical staff. Dr Linder, a native of Hungary and a graduate of Bellevue Medical School in 1896, has been associated with the Jewish Hospital for twenty-nine years. He is also chief surgeon of Israel Zion Hospital, and professor of clinical surgery at Long Island College of Medicine. Dr Linder in 1932 was president of the Medical Society of the County of Kings.

Society News—The United Hospital Fund has moved its offices to 370 Lexington Avenue, where the new Associated Hospital Service and the hospital survey operated under the fund's auspices will also have offices.—Dr James C. Healy, Boston, addressed the American Stomatological Society, May 27, on "Allergy and Endocrinopathy, Their Medicodental Relationship." Dr Edward Frankel Jr. was elected president at the annual meeting.—Dr Claus W. Jungblut and Raymond L. Zwemer, Ph.D., among others, presented a paper before the Society for Experimental Biology and Medicine, May 15, on "Inactivation of Diphtheria Toxin in Vivo and in Vitro by Crystalline Vitamin C (Ascorbic Acid)."—Dr Walter Timme addressed the New York Roentgen Society, May 20, on "Correlation of X-Ray Findings with Clinical Neuro-Endocrine Symptoms."—Speakers before the New York Pathological Society, May 23, were Dr. Louise H. Meeker on "Leiomyosarcoma of the Uterus," Homer W. Smith, Sc.D., "Filtration and Secretion in the Human Kidney," and Dr. Jean R. Oliver, "The Third Dimension in Pathological Investigation."

NORTH CAROLINA

Medical Library in Asheville—The Asheville Medical Library was opened in June, under the sponsorship of the Buncombe County Medical Society. Dr Julian A. Moore is director and secretary-treasurer for the library, which will be open four hours a day. The committee of the society that organized the library project was composed of Drs. Paul H. Ringer, Julian A. Moore, Alva B. Craddock, George Curtis Crump and Eugene M. Carr.

Infantile Paralysis in Eastern Carolina—Drs. Alexander G. Gilliam and Warren P. Dearing of the U. S. Public Health Service have been sent to North Carolina to aid in fighting the outbreak of poliomyelitis, which has thus far centered in the east central part of the state, it was reported July 7. An Associated Press dispatch dated July 6 says that cases have occurred in sixty-one of the 100 counties in the state since January 1. Three hundred and twelve cases had been reported up to July 6.

Group Hospital Plan Organized—The Hospital Savings Association of North Carolina, Inc., was recently organized with Dr Isaac Hall Manning, Chapel Hill, formerly dean of the University of North Carolina School of Medicine, as president. Mr. Robert Lassiter, a Charlotte manufacturer, is vice president and Mr. J. Lyman Melvin, Rocky Mount, former secretary of the North Carolina Hospital Association, acting secretary. Among the directors are Drs. Paul P. McCain, Sanatorium, president of the Medical Society of North Carolina, Louis B. McBrayer, Southern Pines, secretary of the state society, John B. Wright, Raleigh, Jacob Franklin Highsmith, Fayetteville, John F. Brownsberger, Fletcher, and Byrd C. Willis, Rocky Mount.

OREGON

Date of State Medical Meeting Changed—The annual meeting of the Oregon State Medical Society will be held at Gearhart, September 19-21, instead of September 12-14.

PENNSYLVANIA

Personal—Dr. Francis Joseph Dever, chief internist at St. Luke's Hospital, Bethlehem, for many years, has resigned and will restrict his work to private practice.—Dr. Frank J. Conahan, Bethlehem, has been appointed medical director of Northampton County to succeed the late Dr. Edgar M. Green, Easton.

Philadelphia

Faculty Appointments at Temple—Dr. Charles Leonard Brown, associate professor of internal medicine at the University of Michigan Medical School, Ann Arbor, has been appointed professor and head of the department of medicine at Temple University School of Medicine. Dr. John A. Kolmer, formerly professor of medicine, recently resigned to devote his time to research. Dr. John Lansbury of the staff of the Philadelphia Institute for Medical Research has been made associate professor of medicine, and Dr. Gerald H. J. Pearson has been promoted to be assistant professor of pediatrics at the university.

Advisory Board for Research Unit—A board of six scientists has been appointed as an advisory council to the George S. Cox Medical Research Institute of the University of Pennsylvania. The council will hold annual meetings to receive reports, review the work of the institute, which is devoted to the study of diabetes, and consult with the staff on further investigations, it was said. Members of the board are Drs. James B. Collip, Montreal, Elliott P. Joslin, Boston, Philip Smith, New York, Rollin T. Woodyatt, Chicago, and Oliver H. P. Pepper, Philadelphia. The institute was founded in 1932 with a fund bequeathed by the late Mr. Cox, a Philadelphia banker and manufacturer. Dr. Cyril N. H. Long is director of the scientific staff.

RHODE ISLAND

State Medical Election—Dr. John E. Donley, Providence, was named president elect of the Rhode Island Medical Society at the annual meeting, May 22, and Dr. Roland Hammond, Providence, was installed as president. Dr. James W. Leech, Providence, was reelected secretary.

Personal—Brown University has awarded to Dr. Charles V. Chapin, Providence, the Susan Colver Rosenberger Medal given each year to an alumnus for distinguished service to humanity. Dr. Chapin was superintendent of the department of health of Providence for forty-two years.

SOUTH CAROLINA

Appointments to State Board—Dr Kenneth M Lynch, Charleston, has been appointed to the state board of health to succeed Dr Robert Wilson, Charleston, resigned, and Dr Walter R Mead, Florence, to succeed the late Dr William Eggleston, Hartsville. At a meeting of the board, June 26, Dr Foster M Routh, Columbia, was elected chairman to succeed Dr Eggleston.

Medical College Commencement—Leonard T Baker, LL.D, president of the University of South Carolina, Columbia, made the principal address at the commencement of the Medical College of South Carolina, June 6 when forty-one physicians were graduated. The Ravenel award was presented to Dr Vance Wells Brabham Jr, Orangeburg, for a paper on "Problems of Medical Care."

TENNESSEE

Professor of Medicine Appointed—Dr Hugh J Morgan, professor of clinical medicine, Vanderbilt University School of Medicine, Nashville, has been appointed professor of medicine to succeed Dr Charles Sidney Burwell, September 1. Dr Burwell was recently elected dean and professor of research medicine at Harvard University Medical School, Boston. Dr Morgan is a graduate of Johns Hopkins University School of Medicine, Baltimore.

Dr Burwell Honored—About thirty-five physicians who have served on Dr Charles Sidney Burwell's staff at Vanderbilt Hospital at various times in the past ten years assembled for a reunion at the hospital, June 8. The group made ward rounds and saw a motion picture of the hospital made ten years ago. Dr Burwell entertained with a reception. At a dinner at the University Club Dr John B Youmans was toastmaster and speakers were Drs Walter S Leathers, dean of the Vanderbilt University School of Medicine, Tinsley R Harrison, Hugh J Morgan and Albert Weinstein. Dr Burwell will leave shortly to become dean of Harvard Medical School.

Health at Memphis—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended June 29 indicate that the highest mortality rate (194) appeared for Memphis and that the rate for the group of cities as a whole was 105. The mortality rate for Memphis was the same for the corresponding week of last year and was 108 for the group of cities. The annual rate for the eighty-six cities for the twenty-six weeks of 1935 was 122, as against a rate of 121 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may increase the death rate.

Regional Society Meetings—The West Tennessee Medical and Surgical Association held its forty-fourth annual session at Dyersburg, May 16. Among the speakers were Drs Maecenas B Hendrix, Memphis, on "Immediate Treatment of Industrial Trauma", John E Powers, Jackson, "Treatment and Care of the Rheumatic Heart," and William H Witt, Nashville, "Symptoms Suggesting Hypoglycemia, Diverticulitis, Pernicious Anemia and Subarachnoid Hemorrhage." Dr James L McMillan, Decaturville, was elected president. The Upper Cumberland Medical Society held its forty-first annual meeting at Red Boiling Springs, June 4-5. Among speakers were three Louisville, Ky, physicians. Drs Philip F Barbour, on "Appendicitis in Children", William E Gardner, "Flight Neurosis," and Granville S Hanes "The Source and Treatment of Low Backache", Carl C Howard, Glasgow, Ky, "Thrombi and Emboli" and Howard C Curtis, Wichita, Kan, "Mental Conditions Following Brain Injuries and Skull Fractures." Dr Erbie B Clark, Sparta, was elected president and Zebidee L Shipley, Cookeville, secretary. The Black Patch Medical Society elected Dr William B Dye, Springfield, president at a meeting in Clarksville, June 5. Speakers were Nashville physicians. Drs Albert Weinstein, on disorders of the pituitary gland, William W Wilkerson Jr, treatment of hay fever and asthma, and R. Wallace Billington, spinal and pelvic fractures.

WEST VIRGINIA

Monument to Founders of State Society—The West Virginia State Medical Association has erected a monument to the founders of the association at Rivesville, Marion County. The names of sixteen physicians who sponsored the first meeting, April 10, 1867, appear on a scroll attached to the stone marker. The first secretary of the association was

Dr James E Reeves, who founded the little town of Rivesville. His early association there was the reason for placing the monument at Rivesville. The marker will be dedicated at the annual meeting of the association in 1936.

Personal—Dr Edward T W Hall was the guest of honor at a meeting of the Lewis County Medical Society, Weston, April 9, marking his completion of fifty years of medical practice. Dr Thomas H Blake, Buffalo, has been named director of the division of child hygiene of the state department of health. Dr and Mrs Charles O Henry, Fairmont, celebrated their golden wedding anniversary, May 6. Dr Arthur E McClue has been reappointed state health commissioner for a term of four years. He took office in March 1933. Dr Thomas H Blake, Buffalo, has been appointed director of the division of child hygiene of the state health department. Dr Walter C Swann, Huntington, was elected president of the West Virginia Heart Association at the annual meeting in Wheeling in May.

WYOMING

Hospital Superintendent Appointed—Dr Joseph F Whalen, Green River, has been appointed superintendent of the Wyoming State Hospital, Evanston, to succeed Dr David B Williams, who resigned June 1. Construction is to be started immediately on a new building for male patients, to cost approximately \$90,000.

Outbreak of Smallpox—At least 4,000 persons have been vaccinated because of the recent appearance of several cases of smallpox in Sheridan County, according to *Colorado Medicine*. Free clinics were held by the Sheridan County Medical Society in cooperation with the state board of health, the state and county relief agencies and the county commissioners.

GENERAL

France Bars American Physicians—The parliament of France has passed a law requiring that all physicians and dentists practicing in France shall be French citizens. An amendment deferring enforcement of the law until 1940 was added in the senate. It was pointed out that the decree will probably result in the abandonment of the American Hospital at Neuilly. During discussion of the bill it was brought out that the University of Paris Faculty of Medicine granted degrees last year to 585 Frenchmen and 237 foreigners.

Changes of Status of Licensure—The Connecticut State Board of Health announces that the governor signed an act April 10 restoring the license to practice medicine of Dr Fred Eric C Ramville, Jewett City. The Board of Medical Examiners of Maryland took the following action at its meeting April 29:

Dr Charles Francis Baxter Paterson, N. J. license revoked for willfully falsely knowingly designedly and unlawfully obtaining money by false pretenses. Dr Baxter's license to practice in New Jersey was revoked on the same grounds.

Warning Against Addict—The supervisor of narcotic control of the New York State Department of Health reports that several physicians and pharmacists in various towns in New York have been approached by a man attempting to obtain narcotics. In each instance the circumstances generally represented an emergency arising through a railroad accident or a passenger seriously ill aboard a train. Each time a check for \$5 was presented in payment. The man making these transactions has been described to the New York state police as about 45 years old, 5 feet 10 inches tall weighing 160 pounds, with brown hair.

Shoe Company Stops Use of "Doctor" as Trade Name—The Federal Trade Commission announces that the Arenberg Plotkin Shoe Company, Scranton, Pa. has agreed to cease using the words "Approved by Dr Aren" to designate its products, when the latter have not been approved or sanctioned by a physician of that name. The firm also agreed not to use the word "Doctor" or the abbreviation "Dr" as a trade name for shoes or in any way that may deceive buyers into believing that the shoes were made by a physician's design and contain special features as a result of medical advice, when this is not true. According to the commission's stipulation the firm had stamped the words "Approved by Dr Aren" across the soles of certain shoes sold in interstate commerce.

Impostor "Dr Rogers"—The surgeon general of the U. S. Public Health Service, Dr Hugh S. Cumming, announces that a man representing himself as "Dr Rogers" of the U. S. Public Health Service has recently victimized a Chicago physician, who cashed a worthless check for \$50. The man is apparently familiar with names of officers of the service and some of its work. He is of medium height and weighs about 160 pounds, has dark hair which is thinning, eyes set close

together and wears glasses, is well groomed and neat in appearance, and his knowledge of the service appeared to indicate that he could have been associated with it at some time. He is also said to have much information about medical affairs in general and is well informed about current politics and Washington affairs. The surgeon general points out that the impostor may have gained information, which he is now misusing, while an inmate at the Hospital for Defective Delinquents, maintained by the U. S. Department of Justice, Springfield, Mo., where Surgeon L. M. Rogers was chief medical officer.

Medical Bills in Congress—Change in Status. H. R. 8554, the second deficiency appropriation bill, has passed the House. This bill, among other things, authorizes an appropriation of \$20,000,000 for veterans' hospital and domiciliary facilities. According to the report of the House Committee on Appropriations (H. Rept. 1261), it is proposed to construct 6,835 beds for neuropsychiatric patients, including 134 replacements, 455 beds for the tuberculous, including 300 replacements, 2,276 beds for general medical care, including 800 replacements, and 2,250 domiciliary beds, including 1,400 replacements.

Bills Introduced. H. J. Res. 333, introduced by Representative Gasque, South Carolina, proposes to amend the Emergency Relief Appropriation Act of 1935 to authorize grants to community hospitals. H. R. 8280, introduced by Representative Dorsey, Pennsylvania, proposes to prohibit the burial of the human dead at sea. H. R. 8346, introduced by Representative Whitchel, Georgia, proposes to reenact all laws in effect March 19, 1933, granting pensions to veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection and the World War, their widows and dependents. H. R. 8351, introduced by Representative Whitchel, Georgia, proposes to provide allowances for widows and children of World War veterans who died of disability not acquired in service. H. R. 8461, introduced by Representative Hildebrandt, South Dakota, proposes to provide for the conservation of health among Indians by providing for the completion of the construction of the Sioux sanatorium at Pierre. S. D. H. R. 8656, introduced by Representative Boehne, Indiana, proposes to restore compensation benefits to veterans who served in Russia. H. R. 8665, introduced by Representative Disney, Oklahoma, proposes to authorize an appropriation of \$1,500,000 to construct hospitals for Indians in the state of Oklahoma. H. R. 8740, introduced by Representative McSwain, South Carolina, proposes to reenact all laws in effect March 19, 1933, granting pensions to former members of the military service who were discharged for disability incurred in line of duty, their widows and dependents.

Society News.—Dr. William W. Francis, Montreal, was elected president of the Medical Library Association at the annual convention in Rochester, N. Y., June 18.—Dr. Fritz B. Talbot, Boston, was chosen president of the American Pediatric Society at its annual meeting, May 4, and Dr. Hugh McCulloch, St. Louis, was reelected secretary.—Dr. Roy R. Kracke, Emory University, Ga., was named president-elect of the American Society of Clinical Pathologists at its annual meeting, June 9, Dr. Foster M. Johns, New Orleans, was inducted into the presidency, and Dr. Alfred S. Giordano, South Bend, Ind., was reelected secretary.—Officers of the American Gastro Enterological Association, installed at its meeting, June 10, are Drs. Chester M. Jones, Boston, president-elect, Howard F. Shattuck, New York, president, and Russell S. Boles, Philadelphia, secretary. The next session will be at Atlantic City, May 4-5, 1936.—Dr. Carl Eggers, New York, was elected president of the American Association for Thoracic Surgery at its annual meeting, June 4, Dr. Leo Eloesser, San Francisco, vice president, and Dr. Richard H. Meade, Jr., elected secretary. The next annual meeting will be held at Rochester, Minn.—Dr. Frank Hinman, San Francisco, was chosen president-elect of the American Association of Genito Urinary Surgeons at its annual meeting, June 8, and Dr. James D. Barney, Boston, was installed as president. Dr. Henry L. Sanford, Cleveland, was reelected secretary.—Dr. Benjamin P. Watson, New York, was elected president of the American Gynecological Society, and Dr. Otto H. Schwarz, St. Louis, was reelected secretary.—Officers of the American Orthopedic Association, named at the annual meeting, June 7, are Drs. Hiram Winnett Orr, Lincoln, Neb., president-elect, Frederick J. Gaenslen, Milwaukee, president, and Ralph K. Ghormley, Rochester, Minn., secretary.—At the annual meeting of the American Otolological Society, May 29, Dr. Edmund P. Fowler, New York, was chosen president-elect of the American Otolological Society. Dr. Francis R. Packard, Philadelphia, was installed as president and Dr. Thomas J. Harris, New York, was reelected secretary.—Dr. Frank G. Runyon, Reading, Pa., was chosen president of the American Proctologic Society at its annual meeting, June 10, and Dr. Curtice

Rosser, Dallas, was elected secretary. The next annual session will be held in Kansas City.—Dr. Charles Macfie Campbell, Boston, was named president-elect of the American Psychiatric Association at its annual meeting, May 15, and Dr. Clarence O. Cheney, New York, was inducted into the presidency. Dr. William C. Sandy, Harrisburg, Pa., was reelected secretary. The next annual session will be held at St. Louis.—Dr. James J. Waring, Denver, was elected president of the National Tuberculosis Association at its annual meeting, in Saranac Lake, N. Y., June 26, Drs. James A. Price, Memphis, Tenn., and Frederick H. C. Heise, Trudeau, N. Y., were chosen vice presidents.

FOREIGN

Physician Donates Library.—Dr. Aeneas McDonnell, Queensland, Australia, has recently given about 300 books to the Queensland General Hospital. A special room has been arranged as a library and will be called the Aeneas McDonnell Library. A new operating room in the hospital was recently named for Dr. McDonnell.

Typhoid Outbreak in Rome.—The *Chicago Tribune*, July 5, reported that 1,170 cases of typhoid with twenty-two deaths had occurred in Rome since June 1. It was stated that while the cause of the increase in the disease had not been determined, authorities were sure it was not due to pollution of the water or milk supplies. The upper classes have been particularly affected, while school and college students, troops and the poorer classes of the population seem to have escaped, it was said.

Personal.—Sir James W. Barrett, vice chancellor of the University of Melbourne, has been appointed president-elect of the British Medical Association to succeed the late Sir Richard Stawell, who died April 18.—Prof. Richard Kuhn, director of the Institute for Chemistry in Kaiser-Wilhelm Institute for Medical Research, Heidelberg, Germany, has been awarded the Pasteur Medal by the Societe de chimie biologique.—Mr. Lambert C. Rogers has been appointed professor of surgery at the University of Wales, Cardiff, to succeed Prof. Alfred W. Sheen, who retires on account of age.

Government Services

Funds Asked for Health Survey

The U. S. Public Health Service has asked the division of applications and information of the works progress administration for an allotment of \$3,450,000 to carry out a "health inventory" in fifty cities with special reference to chronic diseases and physical impairments such as infantile paralysis, arthritis, deafness, blindness, Bright's disease and other afflictions incapacitating persons for employment, according to the *New York Times*. It was stated that the study would include a house to house canvas, physical examinations and a survey of medical facilities for the care of the sick, with special reference to the chronic diseases. There would also be an intensive study extending over several years of the importance and effect of given chronic ailments on the capacity of the patient and family to remain self supporting and in other respects to carry on as a useful member of society.

Food Shipments Seized

The addition of coloring materials to alimentary pastes conceals inferiority, a form of adulteration that no form of labeling can correct, states the Food and Drug Administration in reporting its seizures for May. Thirty-seven shipments of these products were seized when analysis showed the presence of soy bean flour, of turmeric, a vegetable dye, or of a yellow coal tar food color. The use of even small quantities of soy flour or of color in flour macaroni is a violation of the Food and Drugs Act. The administration points out that, in cases in which added color does not conceal inferiority, the fact of the presence of artificial color must still be declared on the label of the food containing it. Tomato products made from unfit material, though representing a small percentage of such products on the market, still lead in food law violations. Thirty-three lots were seized in May. Other confiscations included thirty-four sacks of decomposed coconuts, one lot of moldy dried red peppers, two lots of insect-infested canned spinach, 400 cases of wormy and decomposed bottled olives, one lot of rancid condensed milk, 875 gallons of unfit cream en route to buttermakers, 38,000 pounds of moldy and rancid butter, two shipments of decomposed canned anchovies, four of decomposed canned tuna and 400 pounds of tainted fresh shrimp. Three cylinders of nitrous oxide contaminated with other gases, one shipment of substandard epinephrine chloride and two of belladonna extract, and a large stock of different deteriorated drugs.

Vitamins and the British Pharmacopeia

The pharmacopeia commission, which was appointed in 1933 for three years to collect material for the next edition, has reported that it has been actively engaged in preparing an addendum to the British pharmacopeia, publication of which is expected next year. The commission has formed a committee of experts to deal with the vitamins and their preparations. At a meeting of the General Medical Council, which received this report, Dr. H. G. Dain, chairman of the Insurance Acts Committee of the British Medical Association, said that he found difficulty in drawing a line between food and drugs, since the products that contained vitamins would in the ordinary way be foods. He thought that the public and the profession should be taught that vitamins could not be regarded as drugs and that the government should take steps to see that common foods contained the vitamins that properly belonged to them. Sir Henry Dale replied that, although much vitamin research lay on the border line between therapeutics and nutrition, the pharmacopeia did not aim at establishing standards of normal diet. Some vitamins had now been isolated in a chemically pure form. Apart from the need of them in normal diet many patients would require vitamins to be given in the most concentrated form. It was the duty of the pharmacopeia to see that such potent remedies were standardized apart from any question of general policy.

Defense of Civilians Against Air Attacks

It is a grim commentary on our boasted civilization that the defense of civilians against air attacks, which may destroy cities and mutilate indiscriminately men, women and children, is a problem that now exercises the government. At the Royal Society of Arts, Mr. Davidson Pratt, a member of the Chemical Defense Committee, which works under the Committee of Imperial Defense, outlined a scheme, which will soon be published officially. Mustard gas, falling in liquid form like rain and vaporizing to poison all that it contaminates is considered the great danger. As yet there is no efficient cheap gas mask for the public, and efficient uniforms against blistering gases have yet to be devised. Households are recommended that the safest place is upper rooms, closely sealed with mud, if nothing better is available. A Geneva protocol has been signed by a large number of nations and ratified by a smaller number prohibiting the use of gas in war, but experience has shown that not much reliance can be placed on "scraps of paper." Airplanes can drop bombs of any size, which may liberate a variety of toxic agents that act on the human body in different ways. Such gases as phosgene and chloropicrin attack the lungs, tear gases, such as ethylchloroacetate and chloroacetophenone, affect the eyes, organic arsenic compounds, such as diphenylchloroarsine, diphenylcyanoarsine and diphenylamine arsenous chloride, are irritants to the respiratory passages. Others of the vesicant type, such as mustard gas and lewisite, will burn the skin or any other part of the body with which they come in contact, whether as liquid or as vapor. Thus, protection of the whole body is required in the case of these, whereas for others a mask protecting the lungs and eyes is adequate.

Mustard gas, which is heavy, may contaminate objects for days in cool weather before all the liquid has evaporated and objects are safe to handle. The safest thing the civilian can do is to keep within doors as soon as warning of an air raid

is given. This must be done promptly, as an airplane spray gives no warning. To make indoor protection as safe as possible there should be in every house, office or building a gas-protected room or rooms in which the occupants can stay until the all-clear signal is given. The top of the house is the safest place, as the occupants will be above the level of any gas clouds produced in the streets. The room should be made as gas proof as possible by closing up all means of ventilation with materials ready to hand. Fires should be extinguished in the gas-protected rooms. There will have to be provision for people caught in the streets. The idea of extensive underground shelters, proof against explosive bombs and gas, is likely to be feasible only for certain vital services, because of the enormous expense involved. The problem of a cheap simple gas mask that will be fool proof and susceptible of mass production from the materials available in the country is receiving the attention of experts. Decontamination squads will have to be organized to deal with areas, buildings and vehicles that must be quickly freed from gas. The services of laundries will be linked up with these, as their processes may be used for cleansing clothing.

Atmospheric Pollution

Atmospheric pollution is one of the drawbacks of civilization and, among other evils, is regarded as responsible for the notable increase in cases of cancer of the lung that have been observed in England in recent years. The Report on the Investigation of Atmospheric Pollution for the year ended March 31, 1934, has just been issued by the government. It summarizes the results of observations made by seventy-five municipal authorities, five industrial undertakings and one agricultural institution. The figures show a slight improvement on those of last year. The greatest total deposit in any gage was in the city of London, where impurities were deposited at the rate of more than 640 tons in the year per square mile. Deposits of about 100 tons per mile were recorded for large manufacturing cities, such as Leeds, Sheffield and Halifax. Measurements of the concentration of sulphur in the atmosphere have been made at twelve stations. The highest concentrations were found at London, Leicester, Newcastle and Sheffield. The measurement of daylight has been made by a new apparatus, which is largely automatic. The light falls on a photo-electric cell and the resulting current charges a condenser, which, when the charge reaches a certain amount, discharges through a neon lamp, causing an ordinary four figure counter to move forward one unit. When perfected, this method should prove a welcome addition to the means of estimating the loss of light caused by smoke pollution of the atmosphere. The instrument can be fitted with filters so that it may measure either visible or ultraviolet rays.

Exhibition of Means of Noise Abatement

The formation of the Anti-Noise League, with influential medical support, in order to diminish the evil of noise in modern life, has been described in previous letters. The league has organized an exhibition of means of eliminating needless noise, which was opened by the prime minister. Scientists and manufacturers have joined the movement, and the exhibition is intended to educate the public in the prevention of noise and to stimulate cooperation between experts who understand the problem of noise and those who suffer from it. Many of the exhibits have been designed to reduce the noises common in houses, business premises and factories, as well as in public thoroughfares. One device is a "floating floor," which consists of a heavy auxiliary floor supported on a structural floor by an elastic mounting such as rubber springs. The difference between the noises produced by impacts on this floor and on an ordinary floor are demonstrated.

Rôle of the Liver in the Pathogenesis of Migraine

At the February 1 meeting of the Société médicale des hôpitaux de Paris, Etienne and Colleson of Nancy reported their observations as to the part played by hepatic insufficiency in the etiology of paroxysmal migraine and of other more persistent types of this clinical entity. There are three types of migraine. The first includes the familiar attacks. The second includes cases in which a migraine-like condition is more or less continuous, in the form of persistent headache, a feeling especially on awakening of a confused mental state, nausea often without vomiting, fatigue, and inability to concentrate and to work. In the third type the second more persistent migrainous state is interrupted by the severe attacks typical of the first group.

Seventy-five cases (thirty five of men and forty of women) were studied over a prolonged period.

Forty-five persons were given treatment exclusively directed toward stimulating hepatic function, such as alkalis in small doses, especially sodium benzoate, magnesium salicylate, sodium citrate, and vegetable and other cholagogues, for a period of ten days. In the other thirty cases, treatment at Vichy was given in addition.

In seven of the forty-five cases the attacks disappeared completely after the first fifteen days of treatment. In twelve other cases the same result was obtained only after two months. In the remaining eighteen cases the attacks disappeared after a longer interval. Eight cases are not included because they have not been followed for a sufficiently long time. In all, thirty-seven patients of the forty-five who were given only medication as stated were relieved completely of their attacks. Twelve of the thirty patients who also received treatment at Vichy noted complete cessation of attacks after some months. In three others the interval between attacks was much longer than before. There was a marked decrease in the frequency of the attacks in nine cases, and in nine others both the interval was longer and the number of attacks lessened. In patients suffering from the more persistent chronic second type, the first improvement showed itself in the cessation of the acute attacks the slight daily one yielding only after the treatments were systematically taken up again. In women with intermenstrual and menstrual migraine, the latter was more difficult to suppress.

Influence of Cancer of Pancreas on Diabetes

Bickel and his associates of Geneva, Switzerland, reported a case at the January 11 meeting of the Société médicale des hôpitaux de Paris of a man, aged 56, who had a severe diabetes for a year. The glycosuria varied from 200 to 300 Gm a day, with acetonuria associated with an interstitial pancreatitis with resultant hypoplasia of the islands of Langerhans. While under observation, a primary carcinoma of the body of the pancreas developed with metastases in the peritoneum and massive infiltration of the liver. Concomitant with the development of the neoplasm there was a progressive improvement of the diabetes, so that after several months a complete disappearance of the glycosuria and acetonuria was noted. Although a dozen similar observations have been reported, no satisfactory explanation of the phenomenon was offered. A pancreatic cancer, when it involves the islands of Langerhans can possess secretory properties, as in the case reported in 1927 by Wilder and his associates of hyperinsulinemia in a carcinoma of the islands of Langerhans. In the present case the primary neoplasm of the pancreas also presented an excessive secretion of insulin, which explains the marked recession of the glycosuria and acetonuria as the carcinoma developed. The liver metastases, however, failed to show any evidence of secretory activity. The liver, which was almost completely invaded by the neoplasm, undoubtedly

played an important part in the hypoglycemia, thus confirming the work of Mann and Magath and of other Americans that experimental hepatectomy or primary liver cell carcinoma is followed by hypoglycemia. The authors believe that diabetes favors the development of pancreatic carcinoma. Sections from some of the islands of Langerhans showed true adenomatous proliferation, and such a change may be the point of origin of a carcinoma as the result of the irritation of the interstitial pancreatitis and the excess of work the islands are called on to do.

Additional Accidents Following Arteriographies

In recent letters a number of accidents following arteriography were reported. Another paper on the same subject was read at the March 6 meeting of the Société de chirurgie by Wertheimer and Frier of Lyons. Seventy-seven injections were made on sixty-one patients for various types of arteritis (nineteen senile, seven diabetic), aneurysms, Volkmann contracture and other arterial lesions. A colloidal solution of thorium was used in the majority according to the technic of Dos Santos viz, injection under a pressure of two atmospheres except when occlusion is suspected, and then only a few tenths of an atmosphere. Only the accidents are included in the report. One fatal result followed the use of the colloidal thorium solution in a case of Volkmann's contracture of several months' duration in a child. During the injection, a transitory vasoconstriction was noted in the forearm and hand and, at the same time a respiratory syncope, which failed to yield to treatment. No other accidents were noted in using the colloidal thorium solution. In one case, death followed the use of "collothor," another thorium preparation. The patient was a man of 65 suffering from an incipient gangrene of the lower extremity due to obliterative endarteritis. Severe pain followed the injection, and amputation was necessary the following day because of the rapid extension of the gangrene. Death occurred twenty-four hours later. There have been altogether three cases, including the one reported here, following the use of the colloidal thorium solution, hence it cannot be regarded as free from danger.

The members of the society have been requested to report their experiences with arteriography from time to time.

Death from Tetanus as a Complication of Burns

At the January 30 meeting of the Société de chirurgie a case was reported by Louis Bazy in which death from tetanus occurred eight days after admission to the hospital for burns of the third degree involving both lower extremities. A man, aged 34, had fallen against a forge full of blazing coke during an epileptic attack. After thorough cleansing of the burned skin, a dressing of 10 per cent eucalyptus in olive oil was applied. Spasmodic contractions first appeared in the lower extremities on the eighth day and extended rapidly upward until the clinical picture of tetanus became typical. Ten thousand units of anti-tetanic serum was injected into the spinal canal, but death occurred. Tetanus bacilli were found by culture in the serum of the burned area on the right leg. No prophylactic injection of antitetanic serum had been given, because there were no breaks in the continuity of the skin over the burned area.

Bazy believes that one ought to vaccinate against tetanus the same as one does for other infectious diseases. He has carried this out on as large a scale as possible by the injection of tetanus anatoxin once a year. This was done in some of the ambulance centers during the World War, every wounded individual being given 1 cc. of tetanus anatoxin on the first and second days and two more doses on the following days. On being sent back, the wounded were given a ticket showing how much of the anatoxin had been given.

Gosset, in the discussion, stated that a committee appointed by the Academy of Medicine had studied the question of vac-

nation against tetanus in 1931. The conclusions were that immunity against tetanus could be obtained by three injections of the tetanus anatoxin given at intervals of three weeks. He believed that such a method should be recommended by the Société de chirurgie for more general adoption.

Rouviellois stated that such vaccination was being employed on a large scale in the French army.

National Subscription for Roux Memorial

The friends and pupils of the late Professor Roux of the Pasteur Institute are organizing a memorial fund to be used as an aid to students who are interested in the various divisions of biology. The Pasteur Institute has experienced a severe reduction in income and its present revenues scarcely suffice to pay the salaries of its personnel and to provide funds to carry on research. Hence it has become necessary to ask the medical profession in general and nonmedical admirers of the Institute to "do their bit" in helping to carry on the research work by buying books containing 100 coupons of one franc (about 7 cents). The committee in charge of the Roux Memorial Foundation will have at its head the president of France. Those willing to aid this worthy cause have been asked to send contributions to Mr. Dufaure, 205 rue Vaugirard, Paris.

Results of Diphtheria Vaccination in School Children

Dr. Poulain of St. Etienne reported at the February 5 meeting of the Academy of Medicine of Paris, the results of vaccination of 6,000 school children with the Ramon anatoxin. A few severe local and general reactions were noted in older pupils but none below the age of 6 years. The dose, 60 units is given in two or three injections (1 cc each of 60 units). Only one case of diphtheria was observed among 6,000 children who were thus vaccinated. The higher the number of units given, the more certain is the prophylaxis. No deaths have occurred in children immunized with 40 units or more. In children between the ages of 2 and 6 years given doses varying from 5 to 35 units, the risk of an attack of diphtheria is one-fourth and the risk of a fatal issue is one-twelfth that of non-vaccinated infants.

With the tendency to give a dose of 60 units in a single injection, one can foresee that the mortality from diphtheria will diminish markedly and the incidence of the disease even more so. At present, with the cooperation of the teachers and medical school inspectors, one can succeed in vaccinating 85 per cent of the children, but when the harmlessness of the vaccination and its good results become more widely known one may hope that vaccination will become obligatory.

Infantile Tetany Cured by Cervical Sympathectomy

Jung and Mathis, associates of Professor Leriche of Strasbourg, reported a case at the meeting, Dec. 12, 1934, of the Société de chirurgie de Paris.

The patient was a girl, aged 11 years, who at the age of 10 months had attacks of rigidity of the extremities without pylorospasm. When she was 6 years old, similar rigidity, but accompanied by vomiting, appeared every one or two months and more frequently, once a week, during the year preceding her admission to the Strasbourg University Hospital. Calcium was given by mouth and by intramuscular and subcutaneous injections, without any benefit. The same was true of parathyroid extract and calcium gluconate. During the attacks, the contractures of the upper and lower extremities presented the typical signs of a tetany. Preceding this, there was severe epigastric pain and repeated vomiting. The latter continued for several days after each attack. The calcium metabolism was markedly increased. April 24, 1934, the middle right cervical sympathetic ganglion was resected. During the following twenty-four hours the attacks were almost continuous, but their severity was lessened by parathyroid extract. After the second

day there were no further attacks, the extremities remaining flaccid, and there was no vomiting. The calcemia four days after the operation showed a marked diminution as compared to the preoperative analysis. This was still much lower on June 1. A month later, however, there was a recurrence of the attacks during the onset of an attack of scarlatina. The peripheral tetany and the vomiting improved rapidly, following the use of the parathyroid extract and calcium gluconate. Since this recurrence and until the time the report was made in December, there had been no further attacks.

The object of the operation is to reactivate the parathyroid deficiency by indirect action on the cervical sympathetic. The role of the parathyroid in aiding calcium metabolism is well known, and the attempt to stimulate this internal secretion has been successful in combating the hypoparathyroidism to which infantile tetany is due.

May 6, 1935

Review of German Casualties in the World War

A recent letter (*THE JOURNAL*, April 6, p. 1260) contained a condensed medical report of the World War, as it affected the German army and navy. In the meantime, some interesting details have been made known. A careful study reveals that the average annual number of deaths was 461,741, or 34.5 per thousand of the 13,387,000 war participants. In comparison, the number of deaths in the German armies during the Franco-Prussian War was 307 per thousand of the war participants. That the number of deaths per thousand was but slightly higher than in the Franco-Prussian War, in spite of great improvements in the destructive implements of war, was due to the improved protective measures, the better hygienic conditions and the progress in medical science.

The war showed that the idea of military fitness was not given enough latitude during peace times. On the basis of new criteria for the testing of registrants for war service from 20 to 25 per cent of the persons exempted before the war from military duty, because of alleged unfitness for service, were found available for the front (184,142) while more than 50 per cent (470,279) could be used in some of the war services.

The strength of the combined German field and garrisoned forces averaged for the four years of the war about 6,300,000, or about 4,100,000 in the field armies and about 2,100,000 in garrison. The strength of the field armies rose from about 2,500,000 the first year of the war to about 5,000,000 during the fourth year. Over the four-year war period the number of wounded and ill patients receiving treatment by army physicians and surgeons was 27,185,240, of which 19,471,917 cases occurred in the field armies. For each hundred war participants there were 164 cases of illness and forty-three cases of wounding, that is nearly four cases of illness to one case of wounding. Only during the first two months of the war did the cases of wounding exceed the cases of illness. About half of the patients receiving medical treatment entered a military hospital (13,403,131). From the battle fields 7,852,851 wounded and ill persons were taken to the field hospitals and 584,786 directly to their home hospitals. From the field hospitals fewer than half of the wounded and sick (3,547,157) were transferred to their home hospitals. On an average the field hospital trains carried monthly 86,081 patients from the war area to their home hospitals. 66,600 from one field hospital to another, and 86,300 in like manner from the field hospitals to the home area. During the course of the war the field hospitals became more and more developed and were provided with special departments, because the wounded and sick who were transported home remained out of the service for a considerable period. Of the men treated in the field and remaining with their own contingent, 98.7 per cent became again fit for service, of those treated in the field

hospitals, 92.7 per cent, and of those admitted to the home hospitals, 90.0 per cent. The average monthly losses in the field armies, due to sickness, wounds and injuries (including the permanent losses) for the four years of the war were as follows. Of 1,000 soldiers in the field armies, 3.8 were killed in action, 3.8 were reported missing, 2.4 were wounded and 73.1 were reported sick. Of this total of 104.7, 73.1 became again fit for service, in addition, 16.1 returned from their homes fit for service. Thus the field army had monthly a permanent loss of 15.5 per thousand (killed in action, deaths due to disease or accident, missing, unfit for service and the current number on the sick list).

The deaths occurring among persons not treated by army physicians (results of wounds, accidents, disease, suicide) amounted annually to an average of 198,859, or 31.2 per thousand of the total strength of the army, and among the group treated by army physicians the deaths amounted to 101,652, or 16 per thousand (4.6 being due to disease and 11.3 due to wounds). The total number of deaths due to wounds (an annual average of 265,431) and the total deaths due to disease (an annual average of 30,825) were in the proportion of 1:0.12. Accidents caused the death of 1 per thousand of the war participants (during peace times, 0.3 per thousand). The suicide rate was about the same in the various war areas and was twice as high among the home population as among the men in the field. On the whole, the number of suicides was less than half that recorded in peace times. During the four years of the war, 702,778 were dismissed as unfit for service, an annual average of 175,695, or 27.6 per thousand (13.5 wounded, 14.1 patients with disease). In 55.6 per cent of those dismissed on account of disease, the unfitness for service was not due to injuries connected with war service. In the four years of the war, 53.6 out of 1,000 enrolled soldiers were dismissed as unfit for service, of which number 6.8 were mutilated. The total number of men who lost the sight of both eyes was 1,445, of one eye, 10,394. Of the 89,760 mutilated soldiers, 74,630 had mutilated limbs, 56.7 per cent had mutilated upper extremities (left arm 30 per cent, right arm 26 per cent) and 43.3 per cent suffered mutilations of the lower limbs.

Open, or movement, warfare, as was to be expected, is shown by statistics to have caused heavier losses than trench, or position, warfare. The number of cases of wounding in the field armies was 4,814,557 including those killed in action, 5,587,244. In addition 771,249 were reported as missing, and about half of these are assumed to have been killed.

Of the 4,814,557 wounded treated by physicians during the four years, 289,053 or 6 per cent died of that number 61,704, or 1.3 per cent, with the troops, 181,817, or 3.8 per cent in the field hospitals, and 45,532, or 0.95 per cent, in the home military hospitals. Of the 4,525,504, or 94 per cent, who recovered, 7.2 per cent were dismissed as unfit for further service. Concerning the outcome of wounds, it may be said that about one third of the wounded men became again fit for service, most of them having remained with their contingent, a further third returned to the front from the home area, and the final third became fit only for home service or unfit for service, or died.

According to the statistics of the medical report, for 375.8 wounds received on the German side there were 481.6 wounds received on the opposing side and for 53.1 killed in action the opposite side lost 86.2. The medical report shows also that in the World War of 100 wounded 93 recovered, on the average, on either side and 7 died which is evidence of the wonderful progress made in the modern sanitary service.

The side arms sword and bayonet played a smaller part in the infliction of wounds than in former wars. The first year of the war, for one wound inflicted with side arms there were sixty-six gunshot wounds (53.7 in the Franco-Prussian War), in the last year of the World War there were 300 gunshot wounds to one wound with side arms. In the later years of

the war, wounds produced by the artillery exceeded by far those caused by gunshots. It has been estimated that possibly 75 per cent of the wounds inflicted during these years belonged to the former class. In wounds of the neck, trunk, upper limbs and thorax, gunshots were chiefly in evidence, but the wounds of the head, the spinal column and the lower limbs were caused mainly by artillery. In head wounds, the hand grenades played an important part. The wounds caused by shrapnel affected fairly evenly all parts of the body. Two thirds of all artillery injuries were produced by shell fragments, the head and the spine being particularly endangered. The large shell fragments inflicted wounds of the lower limbs, the abdomen and the spine. Traumatic tetanus occurred as frequently at the beginning of the war as during the Franco-Prussian War. Of 1,000 wounded men, 3.8 contracted tetanus. Following the general introduction of tetanus immunization the number of cases declined sharply. During the last two years of the war, the percentage of cases was reduced to 0.4 per thousand wound cases. At the beginning of the World War the case mortality of tetanus was 75 per cent, which was gradually reduced to 51.4. During the war, tetanus antitoxin was injected not only in connection with the slightest injury but also in every operation that was undertaken more than seven days after the first protective inoculation, also in connection with any difficult change of bandages made after that time. Tetanus was more widespread in certain areas of France than in others. Gas gangrene developed in 0.6 per cent of the wounded men, and 35.8 per cent of the persons developing it died. Attempts to prepare a suitable immunizing vaccine were not completed when the war closed.

Incidence and Mortality of Various Diseases

Disease	Cases of the Disease per Thousand Soldiers	Case Mortalities Per Cent
Tuberculosis	5.3	14.4
Typhoid	4.6	10.1
Dysentery	6.1	5.6
Cholera	0.13	51.2
Typhus	0.20	22.5
Diphtheria	1.5	3.0
Influenza	11.9	0.33
Scarlet fever	0.50	4.6
Malaria	4.7	0.37
Measles	0.16	0.56
Smallpox	0.02	4.4

The cases of illness (exclusive of wounds) increased at first rapidly and then gradually declined until the summer of 1918, the falling curve being checked only by the summer and the winter peaks. In the summer of 1918 they reached the highest point in the whole war, owing to the influenza epidemic. As a rule, in the field armies the infectious and transmissible diseases (typhoid, typhus, malaria, dysentery, cholera) and the gastrointestinal diseases were more widespread than among the garrisoned forces, that was true also of influenza and heat stroke. Among the garrisoned troops, on the other hand, venereal diseases, nervous and cardiac diseases, disorders of the respiratory organs—also measles, diphtheria and scarlet fever—were more prevalent than in the field armies. In the east, during the first and second years of the war, the morbidity was higher than in the west but in the Balkans, and especially in Turkey, the morbidity was higher than on the eastern or western front. The tabulation shows the incidence of various diseases and their case mortalities.

The actual figures for a number of the diseases were: smallpox 459 (appeared only on the eastern battle front), typhus 5,982, malaria 120,781, dysentery 155,376, typhoid 116,481, cholera 3,303. As compared with peace conditions, heat stroke showed a high incidence only in August and September 1914.

Of the cases of nervous disease, a total of 613,047 were admitted to the military hospitals. An increase of mental disease was not observed during the war, although the number of psychopaths increased as the war went on, so that during trench,

or position, warfare there was one neurologic patient to ten wounded men. Even after recovery, the psychopaths proved to be unfit for service, exerting, as it were, a contagious influence on their environment and gradually finding their way to the home hospitals. Cases of nephritis did not occur in any numbers until August 1915 but were then observed on both the eastern and the western fronts, doubtless as a result of exposure to heavy rains, combined with severe exertion. Special military hospitals for the treatment of cases of nephritis were provided. Venereal diseases in the field armies were less prevalent than among the troops in peace times, but in the home area the incidence was somewhat greater. There were, however, 713,491 cases, or 28 per thousand.

Owing to the strict discipline, only 80,000 developed injuries from war gases. In the "wind" gas attacks about 9 per cent of the patients died, from gas projectiles about 6 per cent, from explosion of gas mines about 12 per cent, and from mustard gas from 2 to 3 per cent. Mustard gas caused, to be sure, few deaths but prolonged illness. The observation time had to be extended to five days, as the disease symptoms did not appear for twelve hours. Of the men exposed to mustard gas, 20 per cent became severely ill, 20 per cent moderately ill and 60 per cent mildly ill, 38 per cent of the mildly ill became again fit for service during the first week.

Convention on Tuberculosis

The Convention on Tuberculosis was held in Bolzano under the chairmanship of Professor Carpi. The first paper, on "Criteria of Clinical Orientation in the Treatment of Pulmonary Tuberculosis," was presented by Professor Carpi, who brought out that by the treatment of tuberculosis one does not mean the treatment of the infection, for the clinic cannot perform miracles but rather the treatment of the tuberculous disease, or, in other words, of the tuberculous patient. At the start, an exact evaluation of the case is indispensable. The dispensary is the fundamental organization for diagnosis and the protection of society but cannot occupy itself with the evaluation of the therapeutic needs of the patients. There is a need of clinical centers to establish a precise diagnosis, in individual cases, of the type, the evolution and the location of the tuberculous disease. The speaker holds that this task, which is so important, should be reassigned to the hospitals.

The treatment comprises two types: the hygienic, climatic and dietetic type and the intervention type. The speaker still recognizes in climate a valuable therapeutic factor but thinks that it should be considered only in connection with other curative factors. One needs to select the climate in accordance with the clinical aspects of the case. A mountain climate, the benefits of which are undeniable, is not suitable for all cases of tuberculosis but is chiefly valuable in the beginning—pleural and bronchial—types. Other patients derive equal benefits from sanatoriums located in middle and low altitudes. Specific vaccine treatment possibly has been allowed to decline more than it should. Intervention treatment is represented by collapse therapy—not only by pneumothorax but also by various surgical forms. It is a question of an individual and not a general therapy. The indications for it are not found in the cavities but in the forms that lead to the destructive phase, namely the exudative, the infiltrative and the phthisiogenic, which are to a large extent capable of retrogression.

The second topic, "Functions of the Clinics and Hospitals in the Crusade Against Tuberculosis," was presented by Professor Cevolotto. According to the sentiment of the recent congress of Warsaw, dispensaries may be assigned a curative function, which should be limited, however, to pneumothorax.

It is impossible to place precise limits on the functions of dispensaries. A greater freedom should be allowed their directors, because a mere prophylactic function is not sufficient to bring an adequate number of patients to the dispensary. In giving a definition of the various types of climate, one should take account of the fact that it is a question of average climatic conditions, whereas it is a common practice to describe the climate of a very restricted region. The action of a given climate may be best judged from the therapeutic results secured in a large series of cases.

Tuberculosis may be cured also in the hospital, if it is located in a favorable climate, but treatment is not the function of such an institution with reference to all tuberculous patients. The chief function of the hospital is to classify, on the basis of clinical observation, the patients referred by the dispensaries and to determine what is the suitable therapeutic management of the case. According to Cevolotto, the hospital should be intimately associated with the dispensary in the treatment of cases that require intervention therapy. He thinks that, in the crusade against tuberculosis, an organization is feasible similar to that in vogue for prophylaxis against syphilis, in which the director of the dispensary manages likewise the associated special department. Other functions of the hospital are to collect patients gravely ill who, on leaving the sanatorium, desire to return to their own region in order to be near their families, and to treat patients with acute forms on account of which they cannot be moved. A general discussion followed the presentation of the papers.

Congress of Internal Medicine

The Società italiana di medicina interna will hold its forty first congress in Bologna, next October. The following topics will be discussed: (1) clinical classification of types of icterus (Professor Micheli, senator, and Professors Dominici and Allodi); (2) evaluation of the individual constitution (Professor Viola, senator); and (3) mediastinopericarditis, in collaboration with the Società di chirurgia (Professor Zagari).

Appointment of Prof. Augusto Stefanelli

Prof. Augusto Stefanelli has been appointed to the chair of zoology and comparative anatomy at the University of Bari. For his introductory lecture he chose the topic "Biology: Its Historical Development and Its Greater Contemporary Problems." After defending the priority of Italian scientific investigators with reference to certain fundamental problems, he traced the development of some biologic theories down through the centuries, described the period in which evolution and darwinian theories had dominated biologic thinking, and then pointed out the untenability of these theories. He discussed the hypotheses advanced, after the overthrow of darwinism, to explain the evolution of living beings, emphasized "form" as a biologic component of prime importance, and demonstrated the great value of morphologic studies. He considered the present status of the cellular theory and our knowledge of vital activity, biogenesis, sex and the mechanism of heredity, adducing evidence for his belief that forms and structures cannot be explained solely by the action of chemical and physical forces. He stressed that one must not lose sight of the spiritual value of studies of nature, must not become engrossed in an incomplete and often illusory determinism, and must not deny that even science leaves many phases of truth still in the dark.

Deaths

The death of Professor Sante De Sanctis, director of the Clinica neuro-psichiatrica di Roma, has been announced. His publications, such as the treatises on infantile neuropsychiatry, experimental psychology and forensic psychiatry, are used as reference works in scientific circles. Important also are his

works on dreams, the mimicry associated with thought, and the aspects of religious conversion. Italy is indebted to him for the creation of institutions for abnormal and defective persons, aid for persons who suffered mental impairment in the war, and for collaboration in the revision of the penal code. He was absolutely opposed to the sterilization of mental patients, by reason of the damage that such intervention causes to the organism.

Prof. Pietro Bastianelli, director and chief surgeon of Ospedale di S. Giovanni Valdarno, died recently at Florence. During the thirty-five years that he was hospital director he performed more than 16,000 interventions. He had specialized in gastric surgery and was a champion of gastric resection, having performed more than 500 gastric resections. Thirty years ago he was the first surgeon to apply plication (with success) in a case of congenital megacolon.

June 10, 1935

Cancer in Hungary

At a recent meeting of the Hungarian Statistical Society, Dr. Tivadar Széll, ministerial secretary, gave an address on cancer mortality. He said that it seems to be on the increase in the whole world and that this tendency will continue. This increase, however, is not real. Cancer was not less frequent formerly than at present, but it is diagnosed now more frequently than in former times. Today more people live to reach old age, when they are more liable to get cancer. In Budapest the cases of cancer amount to 150 per hundred thousand of population annually. This figure is five times as high as that in the nineties of the last century.

As to the causative agent of cancer there are only plausible theories. Cancer should not be considered an infectious disease in spite of the fact that statistics in Budapest have shown that there are so-called cancer streets and cancer apartment houses, where the number of cancer cases is strikingly large. Interesting observations can be drawn from comparing the cancer and the tuberculosis mortality. Throughout the world, he said, the cancer mortality rises in direct proportion with the fall of the tuberculosis mortality. This is closely connected with the general progress of the people. The higher their culture, the more frequently is cancer diagnosed and the less frequently is tuberculosis found. If things continue to go on as at present, in a few years the number of cancer deaths may be expected to overtake and even surpass the tuberculosis mortality.

The first national cancer statistics in Hungary were made in 1896, but the first in the city of Budapest were made in 1874. Cancer was always higher in Budapest than in the remainder of the country, because in Budapest there are more clinics, hospitals and physicians to study and care for the people. It is interesting that the difference in rate is proportionately less in cancer of the female genitals, as those are the easiest recognizable cancers.

The city of Budapest is divided by the river Danube into two parts, the ancient Buda and the modern Pest, and the occurrence of cancer is considerably more uncommon in Buda than in Pest. Buda is chiefly inhabited by rich people living in villas, surrounded with gardens, while Pest is populated by the middle and poorer classes, living mostly in apartment houses. There are four times as many victims of uterine cancer among women living in poverty than among those living in plenty. In the wards of the hospitals the cancer patients comprise 6 per cent of the patients, while among the private pay patients they account for only 1 per cent. It is a striking feature of the statistics that cancer often occurs in company with tuberculosis. According to the Hungarian statistics cancer is more common in women, but under 20 it is entirely absent. Women are more

prone to cancer at an early age than men, the proportion becomes equal only after 60. In regard to religion, the Jews seem to acquire the disease with some predilection, while the least susceptible are the Greeks.

The distribution of cancer cases by professions is interesting. Particularly prone are workmen in the tar, anilin, briquette and paraffin industries. Of artisans, furriers are most inclined to get cancer.

In conclusion, Dr. Széll said that the future holds some promise that surgical institutes and x-ray and radium laboratories will save more and more cancer patients. The increase of cancer mortality, noticeable at present, is not an unfavorable phenomenon, it is only the consequence of the spread of culture and knowledge whereby the disease is recognized earlier.

Hospital Conditions in Poland

At present 700 hospitals are open to the public in Poland. Of these, the state maintains only forty-three, while out of the remaining 657, 313 are supported by the municipalities, villages and other communities, and 234 by societies, unions, and the social insurance. The total number of hospital beds amounts to 56,830, of which 11 per cent are in the state hospitals, 48 per cent in the municipal hospitals, 35 per cent in the social insurance hospitals and 6 per cent in private hospitals.

The ministry of social welfare is alert in providing the sick with ample hospital accommodation. It calculates that the proportion of hospital beds to each thousand urban inhabitants should be five, while the rate for the rural population should be at least two.

The inhabitants of Poland, according to the 1931 census, number 31,927,773, of whom 23,247,794 are rural inhabitants. According to the minister, the bed requirement of the urban population is 43,400, while that of the rural population is 46,496. Since at present the number of beds amounts only to 56,360, there is a shortage of something over 33,000. At present only the city of Warsaw and the Slaski province are adequately supplied with hospital accommodations. The cities of Cracow and Posnan have 90 per cent of their quota. The bed supply in the rest of the cities and the provinces is between 10 and 50 per cent. Conditions are the worst in Stanislawow, Tarnopol and the eastern counties.

Membership in the Hungarian Scientific Academy

It is most difficult to become a member of the Hungarian Scientific Academy, the requirements being, besides noteworthy scientific work and independent research, a high standard of literary work, personal distinction and nobility of character. Candidates for membership must be recommended by at least six members, and in their recommendation they have to point out the merits of the candidate. There are three grades of memberships: honorary, regular, and corresponding.

At the recent meeting of the Hungarian Scientific Academy, Professor Baron Alexander Korányi was elected an honorary member. For many years he has been the pride of Hungarian medical science. His discoveries ensure his name a well deserved place in the history of medicine.

Dr. Albert Szentgyörgyi was elected a corresponding member. His work in biochemistry has been recognized internationally. In recent years his activities have been in the field of vitamin research. He was the first to separate vitamin C from the adrenal. He discovered that vitamin C is present in the green paprika, and by his instructions it was possible to produce several kilograms of pure vitamin C in crystalline form. He placed at the disposal of foreign research workers a quantity of the pure preparation, whereby magnificent research has been started abroad. Now not only the structure and formula of vitamin C has been established but a foreign factory is producing this compound synthetically.

Marriages

GEORGE TURNER CROUT, Gwinn, Mich, to Miss Frieda Wilhelmina Kusch of Lauenburg, Germany, June 15

COLE D GENG, Green Lake, Wis, to Miss Marjorie de Laughter Scruggs of Asheville, N C, June 15

BENJAMIN SUNDERLAND RICH to Miss Helen Jackson Preston, both of Baltimore, June 15

HOMER B FIELD, Lake City, Iowa, to Miss Viola A Bohmfalk at San Antonio, Texas, June 28

GEORGE H PUTNAM, Slocumb, Ala, to Miss Bertha Mae Thompson in Dothan, June 1

THURMAN SHIPLEY, Cookeville, Tenn, to Miss Helen Cates of Lenoir City, May 29

THOMAS B WOODS, Headland, Ala, to Miss Mirum Christmas of Dothan, May 11

ALEX J ARIEFF to Miss Edith Mendelsohn both of Chicago, June 23

LESTER L LONG to Miss Esther May Payne both of Seattle, June 29

HENRY A JEGI, Galesville, Wis, to Miss Ruby Purple, June 4

Deaths

Thomas McCrae ♂ Magee professor of practice of medicine and clinical medicine, Jefferson Medical College, Philadelphia, died, June 30, aged 64. Dr McCrae was born in Guelph, Ont, Canada, Dec 16, 1870. He received the bachelor of arts degree from the University of Toronto in 1891, where he was a fellow in biology from 1892 to 1894, and where he received the degree of bachelor in medicine in 1895, and of doctor of medicine in 1903. He studied at the University of Göttingen in Germany in 1899. On returning to America he became instructor in medicine at the Johns Hopkins University School of Medicine, Baltimore and in 1901 was appointed associate in medicine and in 1906 associate professor of medicine. In 1912 he went to Philadelphia as professor of medicine at Jefferson Medical College and since that date has been physician to the Jefferson and Pennsylvania hospitals. In 1924 he was Lumsden lecturer at the Royal College of Physicians in London, of which he was a fellow. He was chairman of the Section on Practice of Medicine of the American Medical Association, 1914-1915. From 1916 to 1925 he was secretary of the Association of American Physicians and in 1930 its president. He was a member of the American Philosophical Society. In 1927 the University of Toronto awarded him the honorary degree of doctor of science. Dr McCrae was for years associated with the late Sir William Osler, with whom he collaborated in writing a seven volume "System of Medicine," which he later abridged to five volumes under the name "Modern Medicine" and which he continued to edit after Osler's death. He was also the editor of the eleventh and twelfth editions of Osler's widely known textbook "The Principles and Practice of Medicine." Dr McCrae was devoted not only to the practice of medicine but especially to the teaching of medicine and in both spheres of work he won world-wide renown.

Duncan Campbell Smyth ♂ Boston, Harvard University Medical School, Boston, 1909, member of the American Academy of Ophthalmology and Oto-Laryngology, the American Laryngological Association, the American Laryngological, Rhinological and Otological Society, the American Otological Society, the New England Otological and Laryngological Society and in 1933 vice president of the American Bronchoscopic Society, instructor in laryngology at his alma mater on the staffs of the Symmes Arlington Hospital Arlington, Mass, Massachusetts General Hospital and the Massachusetts Eye and Ear Infirmary, aged 50, died, June 11, of cerebral hemorrhage.

Herman M Johnson ♂ Dawson, Minn, University of Minnesota Medical School, Minneapolis, 1901, member of the House of Delegates of the American Medical Association 1926-1927, 1929-1934 past president of the Minnesota State Medical Association fellow of the American College of Surgeons mayor of Dawson was instrumental in the passing of the basic science law in Minnesota, medical superintendent of the Dawson Surgical Hospital aged 61 died June 19

Pedro Gutierrez Igaravidez ♂ San Juan P R, Universidad de Cadiz Facultad de Medicina Spain 1895, past president of the Puerto Rico Insular Board of Health past

president of the Medical Association of Puerto Rico, member of the Radiological Society of North America and fellow of the American College of Physicians, formerly director of the Institute of Tropical Medicine of Puerto Rico, aged 63 died suddenly, May 24, of angina pectoris

Salmen Korke Siebler, Cincinnati, University of Cincinnati College of Medicine, 1918, member of the Ohio State Medical Association, instructor of pediatrics at his alma mater at one time director of the Clinic of the United Jewish Social Agencies and physician for the Hebrew Union College, aged 40, on the staffs of the Cincinnati General Hospital, Child Guidance Home and the Jewish Hospital, where he died, June 9, of malignant hypertension

John R Wathen, Louisville, Ky, University of Louisville Medical Department, 1898, formerly clinical professor of surgery at his alma mater, member of the Southern Surgical Association, one of the founders and fellow of the American College of Surgeons, at various times on the staffs of the Kentucky Baptist Hospital Louisville City Hospital and St Anthony's Hospital aged 62, died, suddenly, May 25, of heart disease

Thomas Henry Kelley ♂ Chicago Rush Medical College, Chicago, 1903, fellow of the American College of Surgeons, on the staffs of the Illinois Central Hospital Jackson Park Hospital and the South Shore Hospital, aged 53, died suddenly, June 11, in the Sacred Heart Sanitarium, Milwaukee, of coronary sclerosis, angina pectoris and coronary occlusion.

Royal Knight Joslin ♂ P A S Lieut Commander, U S Navy, retired, Newport, R I, Tufts College Medical School, Boston 1917, served during the World War, entered the navy in 1921 and retired in 1932, on the staff of the Newport Hospital aged 51, died June 16, in the U S Naval Hospital, of chronic myocarditis

Jerome L Harrell, Norris City, Ill American Medical College St Louis, 1884, member of the Illinois State Medical Society, past president of the White County Medical Society formerly member of the state legislature, bank president, aged 76 died suddenly May 23 of chronic myocarditis

Edward Henry Frigge, Vincennes, Ind Jefferson Medical College of Philadelphia, 1911, member of the Indiana State Medical Association past president and secretary of the Knox County Medical Society county physician on the staff of the Good Samaritan Hospital aged 59, died, May 18

David Munson Trecartin, Bridgeport, Conn, Dartmouth Medical School Hanover, N H 1894 member of the Connecticut State Medical Society fellow of the American College of Surgeons, on the staff of the Bridgeport Hospital aged 67 died May 27, of myocarditis and chronic nephritis

Benjamin W Stearns ♂ Unadilla, N Y, College of Physicians and Surgeons, Baltimore 1892, University of Buffalo School of Medicine, 1893 at one time health officer of Binghamton, aged 68 was killed May 23, when the automobile in which he was driving was struck by a train

James Heiskell Carpenter, Salisbury, Md, University of Virginia Department of Medicine, Charlottesville, 1897 member of the Medical and Chirurgical Faculty of Maryland, on the staff of the Peninsula General Hospital, aged 61, died, May 20, in a hospital at Baltimore

Floy McEwen ♂ Newark N J College of Physicians and Surgeons, Medical Department of Columbia College, New York 1891 on the staffs of the Babies Hospital Coit Memorial and St Michael's Hospital aged 70 died June 11, of pyelonephritis and prostatic hypertrophy

Max Weinstein ♂ Rockaway Beach, N Y, University and Bellevue Hospital Medical College, New York, 1911 for many years on the staff of the Rockaway Beach Hospital and Dispensary aged 51 was found dead in the garage at the rear of his home May 24

Marion Ulrich, Millersburg Pa, College of Physicians and Surgeons Baltimore 1880, member of the Medical Society of the State of Pennsylvania, aged 83, died April 22 in a hospital at Harrisburg, of pneumonia following an injury received in a fall

John A B Sinclair ♂ Miami Fla. University of Virginia Department of Medicine Charlottesville 1901 formerly a medical officer in the navy served during the World War aged 56 died May 19 in a hospital at Miami Beach, of chronic myocarditis

William C Spencer, Verona Miss Memphis (Tenn.) Hospital Medical College 1892, member of the Mississippi State Medical Association and the Associated Anesthetists of the United States and Canada aged 81 died May 20 of hypostatic pneumonia

James T Reddick, Paducah, Ky, University of Tennessee Medical Department, Nashville, 1880, member and past president of the Kentucky State Medical Association, for many years member and president of the board of education, aged 76 died, May 12

George William Clarke, San Diego, Calif, Harvard University Medical School, Boston, 1904, member of the Illinois State Medical Society, served during the World War, aged 62, died May 14, of cerebral thrombosis and hypertension.

Edwin Leroy Kimball, Spokane, Wash, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1875, formerly county coroner, aged 83 for many years on the staff of St Luke's Hospital, where he died, May 17

John Hardee McGuffey, Greensburg, La, Tulane University of Louisiana Medical Department, New Orleans 1909, member of the Louisiana State Medical Society, aged 64, died, May 1, in Baton Rouge, of valvular heart disease

William Thomas Cooke, Toledo, Ohio, St Louis University School of Medicine, 1933, aged 27, resident physician to St Vincent's Hospital, where he died, May 19, of pulmonary embolism, complicating acute appendicitis

Amos D Olds, East Point Ga, Atlanta Medical College, 1887, aged 73, died, May 25, in the Crawford W Long Hospital Atlanta, of injuries received when the automobile which he was driving was struck by a train

Alexander L Spooner, Luverne, Iowa, Keokuk (Ia) Medical College 1892, member of the Iowa State Medical Society, president of the Kussuth County Medical Society, aged 74, died June 1, of pneumonia

Clarence Christian Craft, Hickory N C George Washington University School of Medicine Washington D C 1909, member of the North Carolina Medical Association, aged 54, died, May 24, of cerebral hemorrhage

Garland Eggleston Faulkner, South Boston, Va. University of Virginia Department of Medicine Charlottesville, 1910, member of the Medical Society of Virginia, served during the World War, aged 47, died, May 30

Thomas Henry Wright, Newark N J, Flint Medical College of New Orleans University, 1901, aged 57 died, May 26, in the Essex County Hospital Cedar Grove, of cerebral arteriosclerosis and cardiorenal disease

Percy Louis Taylor, Springfield Ill, Barnes Medical College, St Louis 1898, member of the Illinois State Medical Society, aged 61 died May 24, in St John's Hospital, of hypertensive arteriosclerosis

Irving Linden Ward, Montague, Calif, University of Oregon Medical School, Portland, 1897, aged 61, died, April 14, in the Siskiyou County Hospital, Yreka of cerebral hemorrhage and arteriosclerosis

Horace L Watson, Montpelier Vt, University of Vermont College of Medicine, Burlington 1887 member of the Vermont State Medical Society aged 72 died May 19, of carcinoma of the lungs and throat

John Armour Kirkpatrick, Chicago Hahnemann Medical College and Hospital, Chicago, 1884 aged 81, died, May 29, in St. Luke's Hospital, of hypertrophy of the prostate and chronic myocarditis

Edwin Parker Sanborn ♂ Bristol, Conn Boston University School of Medicine 1905 served during the World War, on the staff of the Bristol Hospital, aged 58 died, May 21 of coronary occlusion

Alexander D Russell, Dover Tenn University of Tennessee Medical Department Nashville 1901 county health officer aged 60, died May 24 in the Clarksville (Tenn) Hospital, of pneumonia

Louis Joseph Cordonnier ♂ Greenville Ill Washington University School of Medicine, St Louis 1907 past president of the Bond County Medical Society aged 54 died May 26 of coronary occlusion.

Wilbur Paddock Klapp, Philadelphia University of Pennsylvania Department of Medicine Philadelphia 1888 member of the Medical Society of the State of Pennsylvania aged 72 died May 10

W Arthur Minton, Piqua Ohio Louisville (Ky) Medical College 1894 member of the Ohio State Medical Association aged 64 died, May 11 in the Memorial Hospital of hypostatic pneumonia

Alfred Emil Staps ♂ Chicago National Medical University, Chicago 1898 Chicago Medical School 1921 field health officer of the city board of health aged 64 died May 30 of arthritis

Frederick Cleaver Hickok, Brooklyn, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, aged 71, died suddenly, May 30, of arteriosclerosis

Robert Dickey Ross, Wadesboro, N C University of the City of New York Medical Department, 1890, member of the Medical Society of the State of North Carolina, aged 70, died, May 27

Samuel Lawrence McManigal ♂ Garrettsville Ohio, Medical College of Ohio, Cincinnati, 1902, aged 59, died, June 7, in St Luke's Hospital, Cleveland, of streptococcal infection

Jacob Ervin Bartel, Los Angeles, Starling Medical College, Columbus, 1891, aged 69, died, April 24, in the Los Angeles County General Hospital, of pulmonary tuberculosis

Buford O'Neal Joiner, Tennesse, Ga, Atlanta School of Medicine, 1912, member of the Medical Association of Georgia, aged 48, died, June 16, of cardiac decompensation

William Washington McBride, Gleason, Tenn, University of Tennessee Medical Department, Nashville, 1890, aged 76, died suddenly, May 14, of chronic myocarditis

Calvin Thomas Riley, Woodsfield, Ohio, Pulte Medical College, Cincinnati, 1881, aged 82, died, May 9, in Spencer, W Va, of cardiovascular disease and pneumonia

John B Gordon, Bunker, Mo (licensed in Missouri in 1883) member of the Missouri State Medical Association, aged 83, died, April 2, of cerebral hemorrhage.

Elbert Church Fortner, Oakland, Calif, College of Physicians and Surgeons of Chicago, 1886, aged 73, died, April 23, of bronchopneumonia and coronary occlusion

James Gilbert Munroe, Winnipeg, Manrit, Canada Halifax Medical College, Halifax, N S, 1899, aged 62, died, June 4, of coronary thrombosis and pyelonephritis

John Paul Kenny, Youngstown, Ohio, Western Pennsylvania Medical College, Pittsburgh, 1896, aged 62, died, May 17, in Cleveland, of coronary occlusion.

Thomas Henry Connolly, Barrington, R I, Bellevue Hospital Medical College, New York, 1895 formerly state senator aged 62, died, May 20

Orray Lesler Massinger, Bridgeport, Conn., Southern Homeopathic Medical College, Baltimore, 1897 aged 61, died, May 27 of arteriosclerosis

Frank Peter Cox, Wolf Lake Mich, Rush Medical College Chicago, 1897, aged 62, died, May 29, as the result of a maxillary sinus infection

J Henry O'Neill, Morgan City, La., Louisville (Ky) Medical College, 1896, aged 66, was drowned, May 9, when he jumped into the river

John Septimus Cadwalader, Meadville Pa Western Pennsylvania Medical College, Pittsburgh, 1901 aged 69, died, May 7, of heart disease

Albert F Meyer, Cleveland, Western Reserve University Medical Department Cleveland 1883 aged 73 died, May 16 of cerebral hemorrhage

Robert Greenleaf Whitlock, San Pedro Calif, Cooper Medical College, San Francisco 1907 aged 55 died April 22 of coronary thrombosis

Alfred B Jones, Lebanon Ind Medical College of Indiana, Indianapolis, 1887 aged 77 died April 14, of pernicious anemia and chronic nephritis

Frank Kaufhold ♂ Newark, N J Cornell University Medical College New York 1906, aged 51, died June 17, of coronary thrombosis

Anna Lipnowski Krygier, Ormond Fla, Universite de Geneve faculte de medecine, Geneva, Switzerland, 1896 aged 68 died April 16

William Holland Henderson, Portsmouth, Ohio University of Cincinnati College of Medicine, 1928 aged 31, was found dead May 14

Francis Clifford Smathers, Punxsutawney Pa, Jefferson Medical College of Philadelphia, 1905 aged 57 died May 7, of leukemia

Robert D Matchan, Minneapolis, Hahnemann Medical College of Philadelphia 1879 aged 80, died, May 12, of myocarditis

Wade W Lawrence, Cambridge Ohio Medical College of Ohio, Cincinnati 1903 aged 55, died April 23, of erysipelas

James Alexander Duguid, Vanceboro N C North Carolina Medical College, Charlotte, 1905 aged 56, died, April 11

Alexander Ramsey, Winterset, Iowa College of Physicians and Surgeons Keokuk 1886 aged 78, died April 26

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nositum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

O K Magnesum Mineral Water—O K Mineral Water Co. Enfield, Ill. Composition Essentially Glauber's and epsom salts with smaller amounts of common salt calcium sulphate and carbonate and traces of silica and sodium nitrate, in polluted water. Adulterated because of filthy or decomposed animal or vegetative substance present misbranded because quantity not plainly stated on package, misbranded, further because fraudulently represented as a cure for kidney and liver troubles rheumatism malaria all forms of stomach trouble etc.—[N J 21792 September 1934]

McMahon's Solution of Calcium Croosote—McMahon's Mfg Co., De Ridder, La. Composition Essentially a calcium and croosote compound (3 per cent) water (97 per cent) and croosote (5 minims per one half fluid ounce). For coughs sore throat bronchitis etc. Fraudulent therapeutic claims.—[N J 21794 September 1934]

Koch's Mentholone Ointment—Dr. Koch Vegetable Tea Co., Winona, Minn. Composition Essentially, small amounts of menthol camphor and eucalyptol in petrolatum and paraffin. Adulterated as to strength and purity because not antiseptic, as claimed misbranded because of fraudulent therapeutic claim for the stuff as an antiseptic and a cure for catarrh hay fever croup pneumonia, etc.—[N J 21804 September 1934]

Koch's Sopt O Cido—Dr. Koch Vegetable Tea Co., Winona, Minn. Composition Essentially small amounts of zinc chloride, saccharine, formaldehyde and acid volatile oils including peppermint thymol and menthol with alcohol glycerin and water, dyed red. Adulterated because not of strength and purity professed and not antiseptic and germ-destroying as claimed misbranded because of fraudulent therapeutic claim as to efficacy in tonsillitis sore throat etc.—[N J 21804 September 1934]

Koch's Cold and Grip Tablets—Dr. Koch Vegetable Tea Co., Winona, Minn. Composition Essentially per tablet acetanilid 213 grains caffeine 0.24 grain phenolphthalein and extracts of plant material including cinchona with starch and calcium carbonate. Misbranded because below professed standard and quality as 2½ grains of acetanilid was claimed for each tablet whereas not more than 2½ grains of it was present also misbranded because fraudulently represented as a cure for la grippe.—[N J 21804 September 1934]

Koch's Rolatam Hoaling Salva—Dr. Koch Vegetable Tea Co., Winona, Minn. Composition Essentially zinc oxide and a small amount of carbolic acid, in petrolatum. For salt rheum eczema sores boils, leprosy caruncles etc. Fraudulent therapeutic claims.—[N J 21804 September 1934]

Koch's Mustard Ointment—Dr. Koch Vegetable Tea Co., Winona, Minn. Composition Essentially volatile oils including those of mustard wintergreen and red pepper in petrolatum. For croup pleurisy bronchitis and sore joints. Fraudulent therapeutic claims.—[N J 21804 September 1934]

Koch's Vegetabilia Family Tea—Dr. Koch Vegetable Tea Co., Winona, Minn. Composition Essentially plant material including scenna sassafras coriander fennel licorice, uva ursi and sage. For blood, stomach liver and kidney disorders etc. Fraudulent therapeutic claims.—[N J 21804 September 1934]

Hart's Swedish Asthma and Hay Fever Medicine—Hart's Swedish Asthma Medicine Co., Buffalo, N. Y. Composition Essentially potassium iodide with glycerin flavoring and coloring. Misbranded because of claim, Pure grain alcohol 4 per cent when no alcohol was present misbranded also because of fraudulent therapeutic claims.—[N J 21783 September, 1934]

Primley's Extract of Sarsaparilla—McKesson-Churchill Drug Co., Peoria, Ill. Composition Essentially potassium iodide plant drug extracts including a laxative drug and alcohol sugar and water. For scrofula, chronic sore eyes jaundice liver complaint, female disorder, syphilis, rheumatism etc. Fraudulent therapeutic claims.—[N J 21784 September 1934]

Hyssop Compound—Hyssop Medicine Co., Chicago. Composition Essentially plant drug extracts including a laxative, with potassium iodide, alcohol (13 per cent by volume) sugar and water. For nervous troubles hysteria sexual weakness scrofula etc. Misbranded because alcohol declaration was incorrect and also because of fraudulent therapeutic claims.—[N J 21785 September 1934]

National Antacid Powder—National Drug Co., Philadelphia. Composition Label declared bismuth subcarbonate 1 part baking soda, 2 parts calcium carbonate precipitated 2 parts magnesium oxide, 2 parts. Analysis of two specimens showed one contained 13 per cent less bismuth subcarbonate and another 18 per cent less than declared on label. Adulterated and misbranded because below professed standard and purity since label represented bismuth subcarbonate was one-seventh of the article, whereas it was less.—[N J 21808 September 1934]

Ormovin Wine of Cod Liver Extract, Etc.—Ormont Drug & Chemical Co., Inc., Long Island City, N. Y. Composition Plant drugs including malt, wild cherry and nux vomica with sodium hypophosphite (0.6 per cent) manganese hypophosphite (0.09 per cent), iron hypophosphite (0.06 per cent) alcohol, sugar and water. For coughs lung and bronchial affections, debility etc. Fraudulent therapeutic claims.—[N J 21789 September 1934]

Aspiral—Charles M. Hick & Co., Chicago. Composition Tablets each containing essentially 45 grains of aspirin, with phenolphthalein. For toothache, earache rheumatism, etc. Fraudulent therapeutic claims.—[N J 21791 September, 1934]

Phytamin Tablets—Phytamin Corporation, Battle Creek, Mich., and New York. Composition Brown sugar-coated tablets containing chiefly calcium phosphate iron phosphate plant drug extracts small amounts of sodium potassium, iodine and carbonate compounds volatile oils including cinnamon and cloves, a fixed oil starch and yeast. For anemia indigestion, nervous troubles, neurasthenia, etc. Misbranded because claims as to vitamin content were false and misleading and because of fraudulent therapeutic claims.—[N J 22184 September 1934]

Red Heart Blood Tans—Reese Chemical Co., Cleveland. Composition Essentially iron and calcium carbonates, zinc phosphide and plant drug extracts including nux vomica and a laxative drug. For blood and nerve disorders. Fraudulent therapeutic claims.—[N J 21786 September 1934]

Tru Knif Ads—Tru Lax Mfg Co., Newark, N. J. Composition Essentially peppermint oil, a pungent substance such as red pepper and a trace of an alkaloid, in a mixture of sugar starch and gum. For bronchitis asthma coughs catarrh, etc. Fraudulent therapeutic claims.—[N J 21782 September 1934]

Thor's Vitamin Compound—Thor Pharmaceutical Co., Atlanta, Ga. Composition Essentially yeast phenolphthalein nux vomica and compounds of iron copper manganese calcium magnesium, sodium and potassium. For anemia acid stomach constipation, nervousness etc. Fraudulent therapeutic claims.—[N J 21805 September 1934]

Faminox—Drug Store Products Inc., Cleveland. Composition In each tablet acetphenetidin 24 grains aspirin 23 grains and small amounts of caffeine and phenolphthalein. Misbranded because label did not show acetphenetidin to be a derivative of dangerous acetanilid and also because of fraudulent claims as a remedy for certain female disorders etc.—[N J 21809 September 1934]

Schwinds Rose Hoaling Salva—Schwind Laboratories, Sioux City, Iowa. Composition Essentially a lead compound incorporated in a fat. For sores infection piles frost bite etc. Fraudulent therapeutic claims.—[N J 21811 September 1934]

ANOTHER POSTHUMOUS TESTIMONIAL!

ALLENTOWN MORNING CALL, MONDAY, MAY 27, 1935

LOCAL LADY TOOK NATEX YEAR AGO
—HAD GOOD HEALTH EVER SINCE

Was only medicine this high
ly respected German resi-
dent ever took that brought
permanent lasting relief

It is the most remarkable fact that
the late Mrs. Mary Deemer, who
died May 25, 1935, at the age of
68, after a long illness, had
been suffering from a severe
case of rheumatism for many
years. She had tried many
different remedies, but none
gave her any relief. She was
in great pain and was unable
to do any work. She was
very weak and was losing
weight rapidly. She was
very anxious to get well and
was very grateful to the
doctors who had treated her.

Mrs. Mary Deemer

Mrs. Mary Deemer of Allentown, Pa., stated that she found 'Nutex' the only 'patent medicine' that really gave relief. Mrs. Deemer died May 25, 1935. Her testimonial was published in the Allentown Morning Call May 27, 1935. On the same page and but three columns removed from the testimonial was Mrs. Deemer's death notice.

Deaths

DEATHS
Mrs. Mary Deemer, 68, of Allentown, Pa., died May 25, 1935, at the age of 68, after a long illness. She was buried in the Allentown cemetery.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

DIAGNOSIS OF APPENDICITIS

To the Editor—Will you be good enough to send me a list (with description) of all the important signs (not symptoms) that may be elicited in all types of appendicitis? I will appreciate the favor.

M D West Virginia

ANSWER.—The so-called signs of appendicitis are more useful in the atypical, subacute or chronic forms in which the classic symptoms are absent and the study of the reflexes is more essential. The abnormal position of the appendix accounts for many errors of diagnosis. The most important signs are based on local tenderness and muscular rigidity.

Most of the signs are classed as eponyms under the names of the authors.

I Local Signs of Inflammation—

Inspection 1 A tender swelling or tumor in the right lower quadrant due to either gaseous distention, thickening of the bowel or abscess.

2 Przewalsky's sign A swelling above Poupart's ligament composed of glands around the circumflex artery.

3 Restriction of the abdominal respiratory movements, especially on the right side, due to reflex tenderness of the muscles.

4 Flexion of the right thigh. Marcus explained that it was due to an inflamed appendix overlying the psoas muscle. Rutherford Morrison believed it was due to a retrocecal appendix abscess with inflammation extending into the psoas sheath.

Palpation

A Cutaneous hyperesthesia 1 Hyperesthesia and hyperalgesia. These may be elicited by lightly stroking the skin over the region of the appendix with the forefinger or a pin and by pinching it. It is of value if positive and is especially striking if the appendix is close to the abdominal wall and distended. It is usually negative when the appendix is deeply placed in the abdomen or lying in the pelvis. Its absence may denote gangrene in an initial appendicitis.

2 Livingston's sensitive triangle. There may be localized hyperesthesia in a triangle bounded by a line from the umbilicus to the highest point on the crest of the ilium below by a line from the latter point to the spine of the right pubis and medially by a line from this point to the umbilicus. Sensitive skin reactions obtained by pinching between the finger and the thumb, whose greatest intensity is at the center of the triangle, are for and if outside the triangle are against appendicitis.

B Superficial tenderness 1 Blumberg's sign This consists of deep momentary pressure over McBurney's point with sudden release of pressure producing sharp pain. This is a sign of peritoneal inflammation.

C. Deep tenderness This varies with the location of the appendix. It is usually nearer the base than the tip. 1 McBurney's sign The greatest pain or maximum tenderness as determined by the pressure of one finger is between $1\frac{1}{2}$ and 2 inches from the anterior superior spine of the ilium on a straight line drawn to the umbilicus.

2 Clado's point The maximum tenderness is where the interspinous line crosses the right rectus margin.

3 Lanz's point The junction of the right and the middle thirds of a line drawn between the two anterior superior spines.

4 Lotheissen's point The maximum tenderness is 2 inches or two fingerbreadths downward from McBurney's point and at right angles to the spino-umbilical line.

5 Morris's point Tenderness at a point on the spino-umbilical line just at the outer edge of the rectus muscle.

6 Aaron's sign Referred pain or tenderness in the epigastrium, umbilical region, left hypochondrium and precordial or left inguinal region induced by continuous pressure over McBurney's point and pyloric spasm, which may be observed under the fluoroscope.

D Tenderness elicited by rectal palpation 1 Wachenheim and Reder's sign There is pain or tenderness in the right iliac fossa over the ileocecal area on rectal palpation with the finger tip directed upward and to the right, in the absence of an abscess.

E. Tenderness over the appendix produced by pressure elsewhere.

1 Rovsing's sign There is pain over McBurney's point on palpating or massaging the descending colon. It is explained

as producing increased air pressure within the cecum or reflex peristaltic action originating at a distance and proceeding directly to the appendix.

2 Chase's sign Similar to the Rovsing sign but elicited by pressure on the transverse colon.

3 Bastedo's sign Pain over McBurney's point, produced by inflating the colon with air by rectum, and subsidence of pain when the air is released. The degree of pressure required can be measured by a manometer.

4 Sorensen's sign With the patient in the supine position with the thighs flexed, one presses on the hepatic flexure of the colon and has the patient cough. Pain over McBurney's point in appendicitis is due to the pressure of gas downward in the ascending colon.

Percussion 1 Gregory's sign Percussion of the left half of the abdomen corresponding to McBurney's point produces pain over the appendix, usually at McBurney's point. Percussion over the descending colon is less likely to produce it. Similar to Rovsing's sign.

2 Murphy's "piano percussion" is used to demonstrate a small quantity of fluid or exudate in the abdominal cavity resting on the hollow viscera. The right lower quadrant of the abdominal wall is struck by the four fingers one after the other beginning with the fourth. There is absence of the tympanitic note obtained by ordinary percussion.

3 Klemm's air cushion Local tympany in the right lower quadrant, which corresponds to the gaseous distention of the cecum and ascending colon often observed in roentgenograms in chronic appendicitis.

II Tenderness elicited by change of posture, or muscle tenderness—

1 Ott's sign When the patient is on his left side there is a feeling of distress and of a painful dragging sensation as if a heavy body in the abdomen had fallen to the left, sometimes referred to as the "mesenteric pull."

2 Tressder's sign The prone position allows the cecum to fall away from the inflamed appendix and gives relief from pain.

3 Meltzer's sign Marked tenderness when pressure is made over McBurney's point with the patient supine, arms elevated, knees partly flexed and the right leg is extended, kept rigid and gradually elevated, thus impinging the appendix between the abdominal wall and the belly of the psoas muscle. Observed in 10 per cent of chronic cases.

4 Sattler's sign In the sitting position the patient raises the extended right leg (with aid if necessary) while the assistant supports the back. The cecum is then pressed between the abdominal wall and the psoas muscle. In appendicitis a sharp pain is felt at the junction of the right and the middle thirds of a line uniting the iliac spines.

5 Drosin's four postures (a) Supine A sudden push to the right of a line one half way between the umbilicus and the ensiform process at the end of expiration if positive means adhesions.

(b) Sum's position With the patient on the right side, the cecum and the appendix are brought upward under pressure by palpation.

(c) Supine The right leg supported at the knee and the left extended bring the appendix and the cecum upward, increasing tenderness and rigidity.

(d) When the abdomen is relaxed between expiration and inspiration, bimanual pressure over both sides of the abdomen will give differentiation.

6 The obturator test The right thigh is rotated internally at the hip joint and the inflamed muscle is put on the stretch.

7 Cope's sign The psoas muscle is stretched by extending the thigh. The two latter tests depend on the proximity of the appendix and the presence of peritonitis.

8. The femoral test (Cope) This is elicited by compression of the femoral artery in Scarpa's triangle on the right side, thus producing pain by increase of tension at the level of the pelvic brim. The test may be of value if the appendix is lying at that site or if tender iliac glands exist.

III Pain or tenderness due to hypersensitive nerves and referred pain—

1 Gray's sign If one presses with the point of the finger about $1\frac{1}{2}$ inches below and to the left of the umbilicus, one can frequently elicit tenderness there. Occasionally at the tender spot there seems to be a small aperture in the rectus sheath, which may correspond to a terminal branch of the eleventh dorsal nerve. Pressure is made over the appendix and then it is repeated on the left side when the pain is found to be absent or lessened.

2. Morris's sign Hypersensitiveness of the right group of lumbar ganglions is determined by making deep pressure on the abdominal wall about $1\frac{1}{2}$ inches to the right of the umbili-

cus and a little below that point. It is not accompanied by a similar sensitiveness in the left group of lumbar ganglions.

3 Dubard's sign. Elicited by pressure over the right pneumogastric nerve along its course in the neck.

4 Gray's shoulder sign. In three cases, pain in the left shoulder was associated with chronic appendicitis reflexly through the phrenic nerve. It disappeared after appendectomy.

5 Miescu's sign. Pain from gentle pressure on the right phrenic nerve in the neck is positive in acute or latent appendicitis and disappears after ice is applied over the appendix. It is ascribed to an ascending right sided lymphangitis, irritating the phrenic nerve.

6 E. V. Mastin observed pain referred to the clavicle in cases of acute appendicitis. This might be reproduced at times by pressure over the appendix.

7 Horn's sign. Traction on the spermatic cord may cause severe pain in the right iliac region.

IV Decrease in muscle tone or atrophy—

1 Volkovitch's sign. There is a localized atrophy and relaxation of the abdominal muscles over the appendix in chronic appendicitis, in contrast to the increased rigidity in the acute form. It is never decreased more than 15 degrees below that of the left side with Exner and Tandler's tonometer.

2 Przewalsky's sign. The right iliac muscle is atrophied from inflammation of the branches of the right crural nerve. One may hold up the healthy leg two minutes but only fifteen seconds on the affected side. The leg is held out straight a few inches above the bed and the examiner's hand is removed.

PHOSGENE POISONING

To the Editor—In the case of a person presumed to have died from phosgene poisoning, can it be ascertained that phosgene was the sole cause of death? If such a diagnosis can be established, will you please state what are the characteristic symptoms, signs and pathologic changes?

PH D N Y

ANSWER—If the person exposed to phosgene gas was in perfect physical condition before such exposure and the atmosphere to which he was exposed was known to be saturated with a heavy concentration of phosgene which he breathed for some time and his death occurred within twenty-four to thirty-six hours following, and during the interval he was completely prostrated, presenting the well known symptoms so closely associated with phosgene, his death could be attributed either directly or indirectly to the effects of such exposure.

From 80 to 85 per cent of all deaths due to poisoning by phosgene occur during the first twenty-four hours after exposure.

Symptoms to be expected are immediate sensory irritation of the respiratory passages accompanied by severe smarting and watering of the eyes, catching of the breath, and violent coughing with a feeling of tightness and pain in the chest, respirations from 20 to 35 per minute, rapid and shallow, attempts to take a deep breath giving rise to severe pain and fits of nausea, retching and vomiting, expectoration, which may or may not be profuse, severe headache and listlessness, with a marked sense of general fatigue.

With the development of edema in the lungs, these symptoms become greatly exaggerated and breathing becomes panting in character and shallow. The ears, lips and progressively the entire face become cyanotic. A bloody frothy discharge may appear from the nostrils and mouth.

The pulse is feeble and of a flickering nature, varying from 125 to 140 a minute. Evidences of circulatory failure become quite apparent. The superficial veins of the face and neck become distended. The skin is cold and clammy. The expression is anxious and distressed. At this stage the patient may rapidly pass into the most dangerous state, becoming more restless, weaker, and assuming a comatose state followed by death.

The pathologic changes depend on the time of death following exposure to phosgene. The essential lesions are pulmonary edema, destruction of the pulmonary alveoli, marked changes in the blood due to the loss of liquid constituents thereby becoming greatly concentrated, enlargement of the right side of the heart and thrombosis.

If death takes place within the first twenty-four hours, the trachea is moderately congested, the congestion extending to the smaller bronchi. The trachea and bronchi may be filled with a yellowish creamy fluid which may be escaping from the nostrils and mouth after death as a frothy blood tinged substance. The lungs are voluminous, heavily edematous and congested with blood. Aerated patches of emphysema and depressed patches of collapse are common especially at the edges of the lung. On section, a frothy serous fluid mixed with blood drips

abundantly from the cut lung. The pleural cavities contain a quantity of straw colored fluid. The heart is generally dilated. The veins are generally distended with blood.

If death occurs on the second or third day, the foregoing conditions are somewhat aggravated.

After the third day the condition of the lungs is changed. Serous fluid no longer drips from cut sections and they resemble the lungs of a case of bronchopneumonia and pleurisy indicating bacterial infection.

SYPHILIS IN PREGNANCY

To the Editor—In August 1934 I consulted you in regard to the treatment of a patient two months pregnant whose husband had a three plus Wassermann for seventeen years in order to insure a healthy baby. During the antepartum period the mother received thirteen injections of neosarsphenamine, a total of 42 Gm. Owing to rather poor cooperation no other form of treatment was carried out. The mother showed a faint trace of albumin all through the antepartum period but no other untoward effects. February 7 an apparently robust baby was delivered and the cord Wassermann was negative (as well as the Kahn test). Atlee and Tyson in their article "Congenital Syphilis: Results of Early Treatment" (*Am J Dis Child* 44:718 [Oct.] 1932) state that babies born of latently syphilitic mothers have potential congenital syphilis and advocate that they be treated from birth on for a period of fourteen weeks with weekly injections of a bismuth compound and sulpharsphenamine in order to prevent its development. Is such a procedure indicated in the handling of this case? Please omit name.

M D New Jersey

ANSWER—A negative cord Wassermann reaction does not, of course, rule out the presence of syphilis in the child, nor does a negative Wassermann reaction of the mother's blood indicate that the child is free from syphilis. On the other hand, a positive cord Wassermann reaction alone is not an indication for antisyphilitic treatment. A simple way of detecting syphilis in a living child when the disease is present is to take a roentgenogram of the long bones. If evidences of osteochondritis are present in the roentgenogram, one may consider this practically pathognomonic of syphilis. However, the absence of syphilis osteochondritis does not exclude syphilis.

In the case cited, the husband had a 3 plus Wassermann reaction. However, as far as is known the patient never had a positive Wassermann reaction or clinical evidences of syphilis except perhaps a miscarriage, which of course by no means implies syphilis. The husband was treated intensively and the patient received some antisyphilitic treatment. Assuming that the patient had syphilis, the injections of arsphenamine that were given to her during pregnancy may have been sufficient to insure the birth of a healthy child. Therefore, this baby should not be treated unless evidences of syphilis appear. The Solomons (U S Interdepartmental Social Hygiene Board, Washington 1922), in a study of the living children born of 236 syphilitic mothers found that 72.5 per cent had no evidence of the disease. If the mother has undergone adequate treatment and the child shows no evidence of syphilis there is no reason to treat the child.

DEMENTIA PARALYTICA

To the Editor—A man aged 50 whose only complaint was difficulty in voiding the urine was referred to the hospital for malaria treatment on account of a positive Kahn reaction in the blood and spinal fluid. Because of the development of a severe hemolytic jaundice the malaria was stopped after he had five chills. Serologic examination of the spinal fluid immediately following treatment showed no response except a fall in the cell count from 67 to 17. Immediately following discharge, symptoms developed that he never had before such as pains in the legs, slight ataxia and increased urinary (no incontinence) difficulty and impotence. Three months after the malaria treatment another examination of the spinal fluid showed no change. Cystoscopic examination disclosed a small median bar. Neurologic examination is negative except for increased reflexes. At present he is receiving a bismuth preparation and iodide. Will you please discuss the prognosis as well as outline any other treatment that may be helpful.

M D Michigan

ANSWER—It may be too early to judge definitely, but at present there appears to be sufficient clinical evidence to consider favorably the malarial treatment in dementia paralytica. The same cannot be said for taboparesis, tabes or cerebrospinal syphilis. Many competent clinicians advise against such therapy, except in dementia paralytica.

As for the manifestations that appeared after the five chills, there are possibilities the certainty of which it is difficult to establish. Perhaps these various symptoms might have developed from a cord lesion without any therapy—simply the usual progressive development of the disease. Since they appeared after the chills, the natural inference would be to associate them in some way.

At present, the precise and exact pathology in tabes is not known, much less the modus operandi of the supposed beneficial effect of the induced malarial infection.

If it is accepted that the primary and essential pathologic condition in tabes is in the vascular supply or the spinal nerves and the cord changes are only secondary, it is conceivable that the malarial infection produced an increased leukocytic infiltration or inflammation and fibrosis of these primary lesions, with increased mechanical pressure and resulting functional disturbance.

According to the evidence as presented, the prognosis must depend on a dual diagnosis, supposed cord lesion and malaria.

Probably the bismuth compound and the iodide will do as much good as any other therapy and less harm.

MEDDLESOME OBSTETRICS—ICE BAGS TO STOP MILK FLOW

To the Editor—A number of women who live near a neighboring town have come to me regarding pregnancy. They tell me that a physician in another town is advising his patients to have something done to bring the confinement on about four to six weeks ahead of the expected time, advising them that the baby will not be so large and consequently they will have a much easier time at the confinement and also advising them that this is the method advised at all the leading hospitals and clinics. I have never seen any literature that confirms his statements and as he loses either at birth or a few days after about one third of his babies I should like to know whether such treatment or handling of confinements is being advocated as he says. Also this man has his patients apply ice bags to the breasts when they have lost their babies through this treatment. I should like to know whether this is considered the proper treatment of the breasts in such conditions. Kindly omit name and address.

M D South Dakota

ANSWER—It is difficult to conceive that any ethical physician would conduct his obstetric practice in as reprehensible a manner as is described. No authority on obstetrics and no obstetric clinic would sanction such pernicious and meddlesome interference with the forces of nature. The great loss of fetal lives is due not only to prematurity but also to the methods employed for starting and terminating labor. If the physicians in the meddler's town do not somehow make him cease his harmful practice, it will not be long before the lay public will raise a cry against the unnecessarily frightful fetal mortality. Perhaps even one or more lawsuits for malpractice may make the physician realize what he is doing.

Ice bags have long been placed on the breasts of women who must stop nursing or whose babies are born dead. The ice bags do not stop the secretion of milk much if at all, but they give relief from the pain that results from the intense engorgement of the breasts. In addition to the use of ice bags it is advisable to keep the breasts snugly bound up. The patient should restrict fluids for a few days and she should take a saline laxative for two or three successive days to insure elimination of fluids through the bowels.

GLANDULAR ENLARGEMENTS IN CHILDREN

To the Editor—What is the significance of glandular enlargements in children particularly those in the cervical and inguinal regions? Does it always denote infection or inflammation? If this question is printed kindly omit name and address.

M D Alabama

ANSWER—There are a number of causes for cervical adenitis in children. Swelling of the cervical glands may be due to a local infection in the tissues adjacent to the glands. Among the common local causes are tonsillitis, tonsillar hypertrophy, peritonsillar or retropharyngeal abscess, dental caries or tumor, diphtheria, eczema, erysipelas, impetigo, contagiosa, laryngitis, pediculosis capitis, rhinopharyngitis, sinusitis, stomatitis, Vincent's angina and regional tuberculosis. Systemic diseases such as leukemia, lymphosarcoma, measles, mumps, rubella, scarlet fever, serum sickness, smallpox and syphilis may cause cervical adenitis. Among the rarer causes are actinomycosis, Brucella infection or Malta fever, glandular fever or infectious mononucleosis, Hodgkin's disease, Mikulicz's syndrome and tularemia.

Among the local conditions that may cause inguinal glandular enlargement are infections of the leg, cellulitis, insect or snake bite, some skin diseases, and erysipelas. Systemic causes may be the same as have been mentioned for cervical adenitis.

As can be seen from the foregoing most of the conditions causing cervical or inguinal glandular enlargement are infections or inflammatory processes although such a condition as serum sickness would not fall into this category. As the exact etiology of some of the rarer mentioned conditions is still unknown, it would be difficult to state the exact reason for the glandular enlargement in these conditions.

PROTECTION AGAINST CARBON MONOXIDE POISONING

To the Editor—An organization with which I am associated is desirous of purchasing from the Mine Safety Appliances Company its pyrotannic acid carbon monoxide detector, for the purpose of accident prevention among employees driving company cars as well as employees in the gas production and distribution department. According to the literature put out by the Mine Safety Appliances Company, the determination of carbon monoxide in the blood can easily be made and with fairly accurate results by supervisors who do not have any medical standing or recognition. I would greatly appreciate your comments regarding the proposed plan as the company wishes to provide its employees with every reasonable precaution against carbon monoxide.

G J RUOFF, Safety Engineer Poughkeepsie N Y

ANSWER—In protecting employees from carbon monoxide poisoning, consideration may be given to the determination of carbon monoxide in the air rather than in the blood. If this seems to be the more practicable plan, it is suggested that the carbon monoxide indicator developed by the United States Navy and sold by the company that sells the pyrotannic acid detector might be found satisfactory for the purpose. The pyrotannic acid method requires 0.1 cc of blood for each determination and it should be taken by persons having such ability and experience, as in taking blood for red cell counts. No great skill or special training is required for satisfactory results, if the blood is available. The method is specific for carbon monoxide poisoning and, if diagnosis is desired, this method is satisfactory.

COMPATIBILITY OF ICE CREAM AND SEA FOOD

To the Editor—Time and time again one hears that it is bad for the health to eat ice cream after sea food. Is there any truth in this statement from the medical standpoint of incompatibility? Kindly omit name.

M D Pennsylvania

ANSWER—We can think of no logical reason why ice cream should not be eaten after sea food, any more than we can see why cream should not be eaten with cherries, or meats with starches. It is possible that a deep student of folklore or of ancient medicine might reveal the source of some of these prohibitions. Some of them can actually be traced back to the days when all foods were classified as warming, cool, dry or moist, so that they might be used in combating the various "humors," which for hundreds of years were thought to be the cause of disease. Today the expression "cool as a cucumber" is used simply because cucumbers happened to be in the list of foods that were cooling to the third degree. Theoretically, they could not be eaten with foods that were warming to the third degree.

DROWSY PERIODS

To the Editor—An attorney aged 70 complains that he is overwhelmed by sleep for a brief period almost every day. His mind is alert. He is physically in good condition. Blood tests and urinalysis reveal no pathologic changes. He has a little prostatic uneasiness but it is not distressing. He shows no other sign of senility. Can you suggest any treatment or regimen that might benefit him?

J A. HAGEMANN M.D. Pittsburgh

ANSWER—The data supplied are rather meager. One would like to know at what time of day the drowsiness comes on and whether there is any relation to meals. If there is no organic basis or abnormal chemical condition, one might try giving ephedrine an hour or so before the expected drowsy period.

STAINS ON TEETH

To the Editor—Will you be good enough to give me some information concerning the dark to black stains on children's teeth sometimes seen? I should like to know the cause of such stains if it is dietary or what it is and what is the remedy other than scaling. Please omit name.

M D Washington

ANSWER—The green to black stains sometimes found on children's teeth are growths of fungi. The stains are most frequently found in mouths with ropy saliva and it is advisable to give the child plenty of water, citrus fruits and milk. This often reduces the amount of stain. Proper brushing of the teeth will do as much as anything to prevent the formation of the stain.

LEAD POISONING FROM HAIR TONIC

To the Editor—Please inform me whether a hair tonic which contains three moderate teaspoonfuls of sugar of lead to one gallon of water and used twice a day on the scalp could have a systemic (lead poisoning) effect. Kindly omit name.

M D Virginia

ANSWER—Long continued use of such application may produce systemic lead poisoning.

Council on Medical Education and Hospitals

ABSTRACT OF MINUTES OF COUNCIL BUSINESS MEETING HELD IN ATLANTIC CITY, JUNE 9

1 The meeting was called to order at 3 30 p m Those present included Drs Merritte W Ireland, Fred Moore, Charles E Humiston, Reginald Fitz, J H Musser, Frederic A Washburn, William D Cutter, Fritof H Arestad and Carl M Peterson and Mr Homer F Sanger In the absence of the chairman, Dr Ray Lyman Wilbur, Dr Ireland presided

2 It was resolved that the minutes of the business meeting of Feb 17, 1935, be approved

3 It was resolved that the secretary by communication commend the University of Georgia School of Medicine for the advancements it has made, and it was further resolved that recognition be accorded to students entering in the fall of 1935

4 It was resolved that the University of Alabama School of Medicine be informed that the Council has taken no action looking toward the discontinuance of its approval of two year schools as an entire group, and that for the present at least each individual school will be judged according to its performance

5 It was resolved that a committee be appointed, consisting of Rev Alphonse M Schwitalla and Drs Herman G Weiskotten and William D Cutter, to study the pattern map used by the North Central Association of Colleges and Secondary Schools and ascertain whether such a map could be made applicable to medical schools

6 It was resolved that the Chicago Medical School be not approved and that the report submitted by the secretary be approved and forwarded to the president of this institution

7 It was resolved that the Eclectic Medical College of Cincinnati be not approved and that the report submitted by the secretary be approved and forwarded to this institution

8 It was resolved that the telegram from the officers of the University of Mississippi be answered by informing them that the University of Mississippi School of Medicine was removed from the Council's list of approved schools July 1, 1934, and that the report of the inspection recently made by Dr Weiskotten, which is before the Council, does not warrant reinstatement.

9 It was resolved that the American Board of Pediatrics, having met with the standards laid down by the House of Delegates, be approved

10 It was resolved that the list of pathologists as submitted be approved

11 It was resolved that, as soon as the American Board of Radiology shall be approved, those physicians at present on the Council's list of approved radiologists shall be notified that this listing is to be discontinued Applications now pending before the Council will be returned

12 It was resolved that a communication be sent to the executive secretary of the American Hospital Association, and also to the American College of Surgeons, asking for their cooperation and urging them to stimulate their local subsidiary organizations to effect a real improvement in the training of interns

13 It was resolved that the Essentials in a Hospital Approved for Interns be amended as follows (Words in italics are being added and section 1 is reworded)

Title Essentials in a Hospital Approved for *Training* Interns

1 Hospitals Eligible for Approval

(This section formerly read) Only general hospitals are eligible which have at least 100 beds with a minimum daily average of seventy-five patients, and which provide a variety of medical, surgical, obstetrical and pediatric patients either in the hospital proper or through suitable affiliations with other institutions

(As amended) General hospitals are eligible which admit at least 2,000 patients per year and/or have a daily average

census of seventy-five patients, and which provide a variety of medical, surgical, obstetric and pediatric patients either in the hospital proper or through suitable affiliations with other institutions New-born infants are included in computing the daily average census but are not counted as admissions

VII Interns

2 INTERN SCHEDULE.—The intern service should cover at least twelve months and should be so arranged as to furnish the interns adequate instruction in medicine, pediatrics, obstetrics, surgery and in the laboratory and x ray departments. *The number of interns should be sufficient to permit each one to study his cases thoroughly The best institutions employ at least one for each 500 admissions* The interns should be selected from medical colleges rated in class A by the Council on Medical Education and Hospitals

14 It was resolved that the lists of hospitals and other institutions for approval or otherwise be accepted.

Book Notices

A Textbook of Biochemistry. Edited by Benjamin Harrow Ph.D. Associate Professor of Chemistry The City College College of the City of New York and Carl P. Sherrin M.D. Sc.D. Dr. P. H. Member of the Staff of St. Vincent's Hospital New York City. Cloth. Price \$6. Pp. 797 with 52 illustrations. Philadelphia and London W. B. Saunders Company 1935.

The subject of biochemistry is growing so rapidly and so extensively that it is becoming increasingly difficult for one individual to write an authoritative textbook adequately covering the entire field. In the present volume the editors have attempted to solve the problem by having thirty specialists in the various branches of biochemistry contribute chapters covering their own particular fields. While this procedure seems to work out satisfactorily in the preparation of a treatise designed for advanced students and others interested in following the latest developments in a particular field, it has certain definite disadvantages when applied to the writing of a textbook for medical and other students who are presumably being introduced to the subject for the first time. A good textbook, like a good teacher, besides stressing fundamental principles, must present for the consideration of the student those facts, critically selected from the vast array of available material, which may be reasonably expected to give him a well rounded, usable knowledge of the subject. In a book by numerous contributors, however, there is always the danger that, unless it is carefully edited, individual authors will devote a disproportionate amount of space to elaborate discussions that contribute little to the needs of the general student at the expense of fundamental principles and well established facts on which the student's understanding of the subject must rest. As an example of such a defect in the present volume may be cited the chapter on immunochemistry in which the author frankly states that "Wells, in his Chemical Aspects of Immunity has so thoroughly reviewed the subject that the writer will attempt chiefly to relate certain advances made since the second edition of Professor Wells' book was written." There is, furthermore, the additional danger that individual authors may be granted more space than is warranted by the contribution which their specialties may be expected to make toward giving the student a well balanced view of the entire field. In the present volume the question as to whether the editors have made the most judicious use of available space is open to serious doubts. While only twenty-five pages are devoted to urine and sixteen pages to hormones, there are eighty-seven pages on proteins of which fifty-five are devoted to "Some Aspects of the Physical

Chemistry of Amino Acids and Proteins." The book contains a great deal of material ordinarily not found in textbooks of biochemistry, so that the editors are enabled to say in their preface that "we are among the first of its readers to have added to our stock of knowledge and to have gained a wider perspective." This very statement, however, points to the limitations of the volume as a textbook of biochemistry for medical students. It will be found much more useful as a reference book for advanced students and others interested in acquiring a more detailed knowledge of biochemistry.

Heart Disease in the Tropics. By H. O. Gunewardene M.B. B.S. D.M. R.E. Consulting Cardiologist Colombo Ceylon. Cloth. Price Rs. 5/- Pp. 101 with illustrations. Calcutta Butterworth & Co. Ltd. 1935.

The purpose of this monograph is "to indicate features in cardiovascular diseases induced by tropical conditions and by diseases peculiar to the tropics." The author's classification of heart disease differs materially from that of the American Heart Association. He lists as types of heart disease rheumatic fever, mitral stenosis, myocardial degeneration, angina pectoris, auricular fibrillation and extrasystoles. This method of classification is confusing, since one patient may have two or more of these entities. The material for the text is drawn from 400 cases observed in private practice and 455 cases from the General Hospital in Colombo. The incidence of rheumatic heart disease as quoted by the author may be estimated at 13 per cent. Syphilitic heart disease comprises only 5 per cent of the total. The degenerative lesions, including high blood pressure, myocardial degeneration, renal disease, angina pectoris and coronary thrombosis, are the common types of cardiovascular disease totaling 50 per cent, which is approximately the same incidence as in the southern part of the United States. It is stated in the preface that ancylostoma infection is comparable as a common cause of heart disease to rheumatic fever of temperate climates. Later the author states that heart disease due to ancylostoma infection might justly be called the "poor man's heart disease" of the tropics. It is doubtful whether there is sufficient evidence in the text to justify these statements. In the statistical data, ancylostoma infection has not been listed as a type of heart disease. Several peculiarities of heart disease in the tropics are pointed out by the author. Rheumatic heart disease occurring in that locality is apparently of a milder form than the rheumatic carditis of the United States and England. Dropsy is said to form at a much more rapid rate in the higher temperatures. Anemia is a pertinent factor in cardiac disability in the tropics. Potassium iodide is badly tolerated in the warmer climates. The text as a whole presents some interesting case histories and brings out a number of important features of the cardiac problem in the tropics. The material, however, is not as well organized as it might be and is somewhat inconclusive.

The Kidney in Health and Disease. In Contributions by Eminent Authorities. Edited by Hilding Berglund M.D. and Grace Medes Ph.D. Research Biochemist in the Lankenau Hospital Research Institute Philadelphia Pa. With the collaboration of G. Carl Huber M.D. Professor of Anatomy of the Graduate School of the University of Michigan Ann Arbor. Warfield T. Longcope M.D. Professor of Medicine in the Johns Hopkins University Baltimore and Alfred N. Richards Ph.D. M.D. Professor of Pharmacology in the University of Pennsylvania Philadelphia. Cloth. Price \$10. Pp. 754 with 163 illustrations. Philadelphia Lea & Febiger 1935.

This single volume probably contains more original authoritative information than any other book on the subject in any language. The book is an outgrowth of a symposium on the structure and function of the kidney in health and disease, which took place in Minneapolis in 1930. The editorial task was initiated by Hilding Berglund and completed by Grace Medes and some of the contributors. For the purposes of this volume the participants in the symposium have revised their contributions and amplified them to some extent to bring them down to date. Several contributions not included in the symposium were added to make the work complete. The list of contributors contains the names of men who have made noteworthy contributions to the subject. Among some of these are the late G. Carl Huber, Franz Volhard, A. N. Richards, James L. Gamble, E. T. Bell, Leonard Rowntree, Longcope, Louis Leiter, M. Herbert Barker, Norman Keith and Kenneth Blackfan. Almost every phase of structure and function of

the kidney in health and disease has been considered, from both the experimental and the clinical aspect. Collectively these contributions constitute a comprehensive and authoritative exposition of existing information. The volume is highly recommended to every physician as an invaluable addition to his library. It is an important permanent contribution to the medical literature.

Physiologie und Pathologie der Wehen. Ergebnisse der Wehenmessung. Von Dr. Tassilo Antoine, Assistent der Univ. Frauenklinik I. Prof. Welbel. Paper. Price 4 marks. Pp. 50 with 43 illustrations. Vienna: Wilhelm Maudrich, 1935.

The author of this monograph undertook a study of the physiology and pathology of uterine contractions. For this purpose he used external hysterography (external tokometry) because he considers the intra-uterine method to be hazardous. For the first time he presents measurements of uterine contractions during the early months of pregnancy and he found that even early in gestation the uterus reacts to oxytocics. The author presents curves obtained not only during normal labor but also in pathologic conditions of pregnancy such as habitual abortion, hydramnios, preeclampsia, eclampsia, uterine atony and menstruation during pregnancy. He also studied the activity of the uterus during the latter days of the puerperium and during periods of severe after-pains. In his investigations of uterine contractions he was especially interested in the tonus of the uterus and the duration and amplitude of the uterine contractions. He found that the most important element was uterine tonicity. He observed that a disturbance in the internal rhythmicity of the uterus with absence of coordination of the separate muscle elements was of great significance in the occurrence of irregular uterine contractions. He further found that all oxytocics act practically in the same way. A fact which is not generally known is that, even after intramuscular injection of an oxytocic, an effect is not obtained in less than a half hour. This monograph is an elaboration of an article which appeared last year in the *Archiv für Gynäkologie*.

The Biochemistry of Medicine. By A. T. Cameron, M.A., D.Sc., F.R.C. Professor of Biochemistry, Faculty of Medicine, University of Manitoba, and C. R. Gilmour, M.D., C.M., F.R.C.I., Professor of Medicine and Clinical Medicine, University of Manitoba. Second edition. Cloth. Price \$6. Pp. 518 with 31 illustrations. Baltimore: William Wood & Company, 1935.

Those who had the pleasure of reading the first edition of this book will welcome the second. The book is a concise review correlating modern and established biochemical data with disease processes. It is presented in a most lucid manner and should be easily followed by those who have not had the opportunity to keep up with the recent biochemical contributions to medicine. Among the subjects receiving the greatest amount of revision are vitamins, endocrine secretions and the chemistry of respiration. Several subjects not touched on in the first edition are diseases of lipid metabolism, glycogen metabolism (von Gierke's disease), aminoacetic acid treatment of myasthenia gravis, pentose nucleotide therapy of agranulocytosis, tyrosinosis, and dimethylphenol treatment of obesity. Other chapters have been conveniently condensed. The book is especially designed for the medical student receiving clinical instruction and the physician who received little or no special instruction in the medical application of biochemistry. The book is a most instructive and concise volume on biochemical work that is of medical interest. It is a simple and readable presentation that serves a most useful purpose for the practicing physician and the advanced student of medicine.

Maladies Infectieuses. Leçons cliniques professées à l'Hôpital Claude Bernard. Par A. Lemerle, professeur à la Faculté de médecine de Paris. Paper. Price 60 francs. Pp. 407 with 23 illustrations. Paris: Masson & Cie, 1935.

This is a collection of clinical studies of a variety of conditions of infectious origin. There are twenty-three lectures or chapters. Among the topics considered may be mentioned tetanus, brucellosis, Rocky Mountain spotted fever and 'fièvre boutonneuse' observed in Paris, infectious nephritis, certain pneumococcal, staphylococcal, streptococcal and meningococcal infections, and unusual cases of septicemia. The presentation is clear and precise and illustrates well the traditional forms of French clinical teaching.

Mother Marianne of Molokai. By L. V. Jacks. Cloth. Price \$2. Pp. 203 with one portrait. New York: Macmillan Company, 1935.

To one interested in leprosy, particularly the Hawaiian story, this book, published approximately 100 years after the birth of Barbara Kopp, retells the tragedy of the disease during the later days of the kingdom and of the early American acquisition, chronicling much of the same material as was recorded in "Damen of Molokai" and "The Samaritans of Molokai" introducing in greater detail, however, the third great ecclesiastical character, Mother Marianne. Mother Marianne Kopp, with six other Sisters of the order of St. Francis, landed in Honolulu Nov. 8, 1883, and almost immediately began the arduous duties of bodily and spiritual ministrations to the theretofore made quately cared for lepers, beginning work first among those segregated near Honolulu. Five years later she proceeded with two Sisters to the large settlement at Molokai where, until her death on Aug. 9, 1918, she devoted her life unstintingly to service among the lepers. The book, while biographic in character, leaves the reader with a sense of having met the leading personality only in the pages.

Medicolegal

Harrison Narcotic Act. When Prescribing Is Selling, Entrapment, Expert Testimony, Evidence.—The defendant, a physician practicing in Oklahoma City and duly registered with the United States collector of internal revenue, was convicted in the district court of the United States for the western district of Oklahoma, under the Harrison Narcotic Act of selling morphine by means of prescriptions not issued in good faith. He appealed to the circuit court of appeals, tenth circuit.

One count in the indictment charged that the defendant wrote a prescription with intent that his patient should through it obtain the prescribed narcotic drug from a pharmacist. The count did not charge, however, that the patient obtained that drug from any source. The trial court said the circuit court of appeals, erred in overruling the defendant's demurrer to this count. The mere writing of a prescription with intent that the person to whom it is given shall obtain the opiate prescribed is not a violation of the statute. Acquisition of the opiate is required to constitute a completed offense.

Another count charged the sale of a narcotic drug to a patient but the undisputed proof showed that not she, but her husband, received the prescription and obtained the drug. Because of that variance between the charge and the proof, the trial court should have sustained the defendant's motion for a directed verdict of not guilty on that count.

A federal narcotic agent who had obtained three prescriptions from the defendant testified that he had advance information concerning the sale of prescriptions by the defendant, which information he had obtained through conversations with addicts. The admissibility of his testimony was challenged, on the ground that it was hearsay. The trial court itself asked the question that elicited the answer to which exception was taken. The question was asked, as the court explained at the time in order to ascertain whether entrapment of the defendant was involved. The truth or falsity of the information that the narcotic agent received and testified to was not an issue and was not drawn into question. Whether the narcotic agent had or had not received such information said the appellate court was a proper subject of proof in order to determine whether the sales to him were made in consequence of a decoy to ensnare the defendant, even though he was otherwise innocent, into the commission of a crime. This is a matter that may be investigated on the court's own motion at any stage of the proceedings. Proof that an innocent person has been entrapped into a violation of law requires that the prosecution be ended. It is against public policy to convict one on evidence obtained in that manner.

After the physician-defendant had testified that he had examined the several persons named in the indictment, to whom he had given prescriptions for narcotic drugs that in his opinion they were suffering from disease, and that he gave the prescriptions to relieve their condition, he proffered the testimony

of three physicians, to show that under the circumstances shown by his records they considered his prescribing of morphine good professional practice. One such witness was asked whether in his opinion a person addicted to the use of morphine is a diseased person. The trial court, however, declined to permit the question to be answered, saying that "the statute prescribes the diseases for which morphine may be prescribed that it expressly provides that merely being an addict is not a disease, and that the question was not one for expert testimony." Another of the defendant's expert witnesses was asked whether he considered it good professional practice to prescribe 10 grains of morphine for a patient on his first call at the office and on his statement that he had been using only 2 or 3 grains daily. Objection by the prosecution was sustained by the trial court, on the ground that the circumstances under which morphine could be supplied was one of law, not for expert opinion. The third of the defendant's expert witnesses testified that he considered addiction to the use of morphine a disease and that it is accompanied by pain. He was then asked whether in his opinion such pain would warrant the administering of morphine for its relief. On objection being made the court allowed the witness to answer the question but stated that the jury would be instructed that administering morphine under such circumstances is prohibited by law, that the statute specifically provides that it may not be given merely for the purpose of relieving pain incident to the condition of an addict. The circuit court of appeals, however, found that the trial court had incorrectly stated the law and unduly circumscribed the testimony. The statute does not prescribe the diseases for which morphine may be supplied. Regulation 85 issued under the provisions of the Harrison Narcotic Act forbids the giving of a prescription to an addict or habitual user of narcotics not in the course of professional treatment but for the purpose of providing him with a sufficient quantity of a narcotic drug to keep him comfortable by maintaining his customary use. Neither the statute nor the regulation precludes a physician from giving an addict a moderate amount of drugs in order to relieve a condition incident to addiction, if the physician acts in good faith and according to fair medical standards. Expert testimony with respect to recognized medical standards and methods of treating patients, such as those for whom the prescriptions were furnished, was admissible because of its bearing on the intent and purpose with which the prescriptions were issued. If the defendant's conduct conformed to fair medical standards, it would indicate good faith; if not it would suggest the dispensing of narcotics for commercial reasons.

A narcotic agent testified with respect to three 'sales' to him that he did not at the time of those 'sales' say or indicate to the defendant that he the agent was an addict, that he said he wanted a prescription, that no physical examination of him was made, and that the prescription was readily furnished on payment for it at the rate of \$1 per grain of the drug prescribed. According to the testimony of the defendant, however, the agent was in a serious physical condition when he came to him, unshaven, unkempt, nervous, and with water running from his eyes. A careful physical examination was made, having particular reference to his pulse, heart beat and nerve reflexes. That the narcotic agent, posing as a patient, confessed that he was an addict using about 2 grains of morphine daily and asserted that he was in great bodily pain. The defendant, according to his testimony, believed that it was necessary to provide morphine for his patient by means of a prescription, to relieve his suffering, and he did so then and on two subsequent visits.

In instructing the jury the trial court intimated that the narcotic agent had no motive for making a false statement and told the jury that it might give to his testimony the same weight and credibility that it would give to the testimony of any other person under similar circumstances. But concerning the physician-defendant, the trial court said:

On the other hand you may in giving consideration to the weight and credibility of the testimony of the defendant you may consider the fact that he is defendant in this case. He has the legal right to be heard in his own behalf and it is your duty to give to the testimony such weight and credibility as you believe under all the circumstances it is entitled to, but, as indicated above you may take into consideration the fact that he is the defendant and that he is charged with a serious offense and you may consider whether or not if the defendant is not

guilty what statement he would likely make, and on the other hand you may take into consideration the fact that if he were guilty what kind of a statement he would make, and is his interest in this case such as would lead him to make an untrue statement to secure his acquittal.

The instruction by the trial court, said the circuit court of appeals, went an arrow's flight beyond the permitted bounds of fair and helpful analysis of the evidence, or comment on it, as an aid to the jury in arriving at a just verdict. It told the jury that there was no motive for the narcotic agent to testify falsely but that there was such a motive on the part of the defendant and intimated in a pointed way that false testimony might be expected from him. This was argumentative and prejudicial.

The prosecution urged that this error of the trial court could not be reviewed by the appellate court, because the defendant had taken no proper exception to the judge's instruction. The circuit court of appeals, however, took a different view of the matter, saying:

A general exception was taken to the charge as a whole but no special exception was directed to any particular part of it. Ordinarily alleged errors occurring during the trial of a criminal case must be appropriately called to the attention of the trial court thus affording an opportunity to correct them; otherwise they are not reviewable on appeal. But an appellate court may correct a serious error involving the life or liberty of an accused in a criminal case although the error was not challenged and preserved for review by proper objection, exception or assignment.

If appellant issued the prescriptions in good faith as a physician believing Bridges [the narcotic agent] to be a bona fide patient for the purpose of curing disease or relieving suffering he was not guilty.

His own testimony was submitted in an effort to establish that fact, and in the very nature of things it was the focal point of his defense. The instruction segregated the testimony and emptied it of effect. We think the error was sufficiently serious that it should be corrected even though no specific exception was taken at the time.

The judgment of the trial court was reversed and the cause remanded for a new trial.—*Strader v United States*, 72 F (2d) 589.

Malpractice Expert Testimony Not Necessary to Support Verdict—The physician-defendant administered roentgen treatments for ringworm on his patient's hand. The first two treatments were followed by abnormal redness of the hand and forearm. During the third treatment the arm pained so much that the patient could not hold it still, but despite her complaints the physician-defendant continued the treatment. When this treatment was finished he told her not to return for other treatments, as he was leaving the city. A burn resulted and the patient was unable to do work of any kind for some weeks and she was forced to consult another physician. She brought suit against the physician who had administered the roentgen treatment.

The patient, as plaintiff, produced no medical expert witness to testify in her behalf, but at the time of the trial, two years after the burns had been inflicted, she had not yet fully recovered the use of her hand and arm and the scars on them were submitted to the view of the jury. On behalf of the defendant a motion was made in effect for a directed verdict. It was contended that, since his liability depended on whether he had or had not exercised proper skill and care, the testimony of medical experts was essential to the plaintiff's case, and she had produced none. The trial court apparently directed a verdict in his favor, and from the judgment entered on it the patient appealed to the Supreme Court of Appeals of West Virginia.

The Supreme Court of Appeals, in reversing the judgment of the lower court and ordering a new trial, said that while the testimony of medical experts is ordinarily necessary in malpractice actions, there are situations in which there is such a want of skill as to dispense with the need for such testimony. The condition of the plaintiff's hand and arm at the time of the trial, its condition immediately following the third treatment, the continuation of treatment by the physician-defendant after knowledge of burning, and his apparent abandonment of the patient, were all circumstances, the court thought, that would have warranted a jury's inferring want of care on his part notwithstanding the absence of expert medical testimony. The trial court erred in not allowing the jury to pass on the issues in the case.—*Buskirk v Bucklev (IV Va)*, 176 S E 603.

MISSOURI STATE MEDICAL ASSOCIATION

Seventy Eighth Annual Meeting Held in Excelsior Springs Mo
May 6 7 8 and 9 1935

DR. T. C. RYLAND, Lexington, Mo., in the Chair

Complications After Operation for Rectal Fistula

DR. WARREN R. RAINEY, St. Louis Surgical proctologists who have a large number of patients with tuberculosis have observed that in many instances the first indication of tuberculosis is the formation of a rectal abscess and fistula, which is followed by active lung tuberculosis. As a result there is an erroneous idea in the mind of the public that operations for rectal fistula may result in tuberculosis. Perirectal glands high in the perineum occasionally become involved by tuberculosis and break down, as do glands in the neck. Fistulous tracts are formed, which present and discharge about the perineum. Unfortunately many such patients are operated on with the idea that the fistula has a connection with the rectum, and in an effort to find an internal opening into the rectum an overzealous surgeon may force a probe through the rectal mucosa and complicate what was originally a tuberculous sinus. Operation on this type of sinus rarely ever results in a cure. Such sinuses occasionally are secondary to a tuberculous seminal vesiculitis. Most failures following operation for simple rectal fistula are apparently the result of incomplete surgery or a lack of knowledge of anatomic and pathologic development in a rectal fistula. The failure is the result of not having located the internal rectal opening. Incontinence most frequently follows operation for perirectal abscess when the rectal sphincter is cut across at the time the abscess is evacuated. Rectal fistulas occurring in the anterior circumference of the anus in the female present a great hazard when completed in a single operation. A low pilonidal cyst sinus may be mistaken for a rectal fistula.

Developments in Renal Surgery

DR. OSWALD S. LOWSLEY, New York A new operation for the repair of a nephrostomy wound after removal of stone in the kidney pelvis uses ribbon gut technic, which consists of passing the ribbon gut through the fibrous capsule of the kidney with a flat needle specially designed for the purpose, and after the application of a thin layer of fat over the bleeding points of the kidney cortex the ribbon gut is tied, causing sufficient pressure to control hemorrhage and not enough pressure to cause necrosis. The ribbon gut is absorbed within three weeks and the repair perfected, thus doing away with the old fashioned mattress sutures, which were so destructive of kidney cortex. In a new nephropexy operation, chrome ribbon gut is fixed in position around each pole of the kidney. Two of the loose ends are tied together. The other needle-studded end of the upper ribbon gut is passed above the twelfth rib and tied in position, elevating the kidney to the desired location so that the ureter is on a slight stretch. The ribbon gut around the lower pole is then attached to the quadratus lumborum muscle thus aiding in the fixation of the previously movable kidney. Repair of ruptured kidney is done by means of pads of fat and ribbon gut placed in any desired position with a flat needle.

Urinary Incontinence

DR. D. K. ROSE, St. Louis The mechanism of normal urination may be divided into seven steps (1) gradual filling, until (2) a mild involuntary bladder wall contraction is instituted by

weight, (3) stimulating an alinement of the internal and external sphincter openings, (4) associated with a contraction of the trigonal muscle, (5) urine entering the posterior urethra flows through the entire length of the urethra afferently, stimulating the bladder to forceful contraction, (6) which by thickening the wall increases the force of the stream until the bladder is emptied, and (7) terminal ejections, emptying the bladder and urethra and leaving a relaxed bladder wall and firmly closed internal sphincter. The chief factors in the act of urination are the expulsion force of the bladder wall, the resistant power of the sphincters, and cerebral inhibition. Cystometric studies show that incontinence or retention of urine is the result of an imbalance between expulsive bladder wall force and the resistant power of the sphincters under normal or abnormal cerebral control. Such imbalance may be neurogenic or myogenic in origin. If neurogenic it may be secondary to central or peripheral nerve change. If myogenic (that is, primary muscle change) it is due to a functional abnormality in the bladder wall or sphincter musculature as a result of some form of prostatectomy or of tumor, fibrous tissue change, outside pressure or foreign body, but with a normal nervous system. By means of cystometrograms the basic alterations can be estimated and therapy instituted to reestablish a normal muscle balance between bladder wall and sphincter tone.

Heart Disease in Children

DR. HARRY M. GILKEY, Kansas City, Mo. From January 1924 to January 1934 at the Children's Mercy Hospital in Kansas City, Mo., my associates and I have cared for 558 children suffering from chorea rheumatic fever and its accompanying cardiovascular damage. We have attempted to study the familial inheritance and incidence, age of primary infection, previous contagion, seasonal incidence of primary infection and reactivation, colds, incidence of tonsillitis, results of tonsillectomy, removal of the foci of infection, length of stay in the hospital, age at which the signs of circulatory insufficiency developed, the cause of death and conditions found post mortem.

Tonsillitis and rheumatic fever play a far more important role in the etiology of endocarditis than does chorea. Uncomplicated chorea rarely had a resultant endocarditis.

Ninety per cent of the chorea patients with rheumatic arthritis developed endocarditis. Tonsillectomy had no effect on the course of chorea, but tonsillectomized patients less frequently developed endocarditis. Psychic trauma was intimately associated with the onset of chorea.

The actual degree of valvular disease is not always important and is not a prognostic point of great importance as compared to the virulence of the infection, the resistance of the host and the number of reactivations.

Although we have no positive proof that the routine removal of tonsils prevents primary manifestations or minimizes reactivations of rheumatic fever, we believe that such a procedure plus a careful study of the sinuses are justified in the type of child included in this study.

Measures to protect children with rheumatic heart disease from the common cold and other infections of the respiratory tract in late winter and early spring, especially those from 6 to 10 years of age, when primary manifestations and reactivations are most apt to occur, is the best form of prophylaxis.

The use of intravenous preparations of hemolytic streptococci with the hope of lessening the hypersensitivity is in the experimental stage but offers much promise.

Quinidine Sulphate Its Actions and Uses

DR. PETER T. BOHAN, Kansas City, Mo. During the past two years, quinidine has been prescribed for seventy office patients. No untoward results have been observed. It has been used to lessen or eliminate extrasystoles, the tachycardias, and paroxysmal auricular fibrillation and flutter. The dosage was 3 grains (0.2 Gm.) from two to five times daily. Patients were advised to discontinue the drug for two or three days from time to time and to observe the effect. The results indicate that quinidine is the most effective available remedy to lessen myocardial irritability. Its use in established fibrillation is questionable. It is definitely indicated in all cases of myocardial infarction to prevent sudden death due to ventricular fibrillation.

The Differential Diagnosis and Treatment of Chronic Appendicitis

DR WARREN H COLE, St Louis Appendectomy for relief of so-called chronic appendicitis should be performed only after a thorough study of the patient's symptoms and signs has eliminated the possibility that another disease may be producing the symptoms. In general, the mechanisms producing the symptoms in this disease may be classified into three groups: (1) obstruction of the lumen by fecalith or stricture, (2) kinking or traction on the organ by adhesions, and (3) sympathetic neuromas. The pain occurring in "chronic" appendicitis or "interval" appendicitis occurs in attacks lasting a few days and recurring at varied intervals. The pain does not radiate posteriorly or downward. Tenderness is constant over the area of pain but is confined to this region except perhaps for a mild tenderness over the liver edge. The pain is mild but is often so distressing as to be almost totally disabling. The presence of fever, vomiting, headache, backache, and pains in the chest or different parts of the abdomen usually contraindicate operation on the grounds of inaccuracy of diagnosis. Distress in the epigastrium with relief by eating or ingestion of alkalis, as is encountered in peptic ulcer, is not infrequently a part of the manifestations of chronic appendicitis. The most common diseases that are confused with this appendiceal lesion are nephropathy, renal calculus, spastic colitis, oophoritis, chronic salpingitis, chronic cholecystitis, and tuberculosis or carcinoma of the cecum. If the pain is present only during menstruation or is much more pronounced at this time, the explanation may lie in disease of the adnexal region. The urine must be examined on numerous occasions. Roentgen examination with the barium meal may be extremely helpful in revealing fecaliths or stricture, but interpretation is difficult and should be attempted only by a trained roentgenologist. The presence of leukocytosis if caused by an appendiceal lesion is indicative of acute appendicitis and not the "chronic" type.

Tumors in the Head of the Pancreas The Value of Cholecystenterostomy

DRS W T COUGHLIN and J M MCCAUGHAN, St Louis This paper is based on thirty-four cases of carcinoma of the pancreas collected from the combined records of St Mary's Infirmary, St Mary's Hospital and Firmin Desloge Hospital of St Louis. The total number of hospital admissions during the ten year period of this report was 67,991. Of these thirty-four patients there were seventeen who were subjected to cholecystenterostomy and seventeen others, nine of whom were not operated on at all and eight who were subjected to various other surgical procedures, such as gastroenterostomy, cholecystostomy and simple exploration with immediate closure of the abdomen as soon as the nature of the lesion was evident. Our report calls attention to the value of internal biliary drainage in malignant or inflammatory obstructions of the head of the pancreas, even though the incidence of such lesions is relatively low, because an analysis of this group of patients obtained from the case records of these three large general hospitals indicates a need for greater emphasis on the importance of this procedure. We feel that external biliary drainage in such patients is deplorable and yet the impression gained from discussing this matter with physicians is that external biliary drainage for the relief of biliary obstructions originating from tumors of the head of the pancreas is not infrequent.

Diagnosis and Surgical Management of Cancer of the Stomach

DR CLAUDE J HUNT, Kansas City Mo About one third of all cancers occur in the stomach. If this annual death rate is to be reduced, it must come through early diagnosis and early operative removal. Reports by Gatewood and Alvarez show that patients present themselves for treatment on an average, from six to ten months after the beginning of gastric symptoms obviously too late in many cases for resection. Many early diagnoses are overlooked because the seriousness of the complaint was not suspected or recognized at the initial examination and the one method of making an early diagnosis was neglected, namely, a careful roentgenologic study. Again when the condition is diagnosed early enough to warrant exploration operation is often not insisted on and the patient is deprived of the only means of relief or possible cure. This attitude concerning the

necessity of operation is due largely to the lack of personal contact with the temporary or more extended beneficial results of radical resection for gastric cancer. To those with even a small experience in this type of surgery the results have been so beneficial, as measured in comfort and extended life, that the operation has been well justified. Gastric surgeons have placed the association between gastric ulcer and subsequent malignancy at from 20 to 25 per cent. Such frequent relationship is denied by pathologists. Cancer does not develop in normal tissue. Some preexisting abnormality or irritant is usually present. Benign lesions, as localized areas of mucosal hyperplasia, papillomas, adenomas and polypi, are much more frequent than formerly suspected and are predisposing factors in malignancy. Horsley has emphasized such relationship and Miller, Eliason and Wright have found malignant cells present in 35 per cent of a series of apparently benign lesions of the stomach found at autopsy. Confinement to the stomach does not long remain, however. Warwick reported forty-three cases in a series of 176 fatal cases of cancer of the stomach in which the disease was still confined to the stomach, death had been due to perforation and peritonitis. The early diagnosis is based on a competent roentgen examination, as there are no signs or symptoms distinctive of early gastric malignancy.

Early Diagnosis in Abdominal Diseases

DR. FRED W BAILEY, St. Louis The intra-abdominal diseases that boast a high yet pregnable mortality may be briefly arraigned: 1 All forms of cancer, 2 Gastric, duodenal or intestinal ulcer, 3 Diverticulitis, 4 Intestinal obstruction resulting from (a) neglected hernias, (b) postinflammatory or postoperative adhesions, (c) pelvic infection, (d) appendicitis, (e) diverticulitis, (f) postoperative ileus, (g) malignant conditions, and so on, 5 Neglected appendicitis, 6 Hepatic infections, bile duct and gallbladder disease, 7 Pancreatic disease, primary or secondary to group 6, 8 Traumatic injuries of the abdomen, penetrating or nonpenetrating, 9 Inefficient pre-operative preparation and postoperative care rank high as mortality promoters in all types of abdominal disease.

The time factor in diagnosis and treatment of acute progressive abdominal lesions, threatening rupture of a viscus and peritonitis, is most essential as a preventive in mortality. Not all abdominal diseases are demonstrable early enough to make preventive therapy and surgery applicable 100 per cent, yet, by the aid of such lay education as organized medicine can ethically disseminate, early recognition of threatened disease would make medical and surgical control practical and efficient as life saving measures. The mortality in abdominal diseases can be reduced thereby not less than 75 per cent. Sixty-six thousand deaths from abdominal cancer alone in the United States in 1930, an ever increasing mortality in acute appendicitis and many other humiliating records seem to justify a renewed agitation for the earliest possible diagnosis in abdominal diseases.

Unusual Case of Foreign Body in the Abdomen

DR. ROLAND HILL, St Louis A well developed married woman, now 64, had had a catheter inserted into the uterus in 1901 to produce an abortion. An abortion promptly followed but the catheter never passed. From this time on the patient complained of low abdominal distress which became aggravated as time passed. In 1927 she consulted Dr Frank D Gorham of St Louis, who made a physical examination. During the gastro-intestinal roentgen examination it was revealed that the catheter had perforated the uterus and was lying in the pelvis in close proximity to the bladder. The patient had lost considerable weight and suffered a great deal from indigestion and pain in the abdomen. The stool contained much mucus and there was an unusual loss of blood at the menstrual period. The catheter was removed by low abdominal operation. When the abdomen was opened it was found to be strongly adherent to the peritoneum of the pelvis and also to the small bowel for about 3 inches as though it were trying to ulcerate into the bowel. On removal, the catheter was found to be of the gum elastic variety and 14 inches in length. All adhesions were carefully separated, the abraded peritoneum repaired and the abdomen closed in layers. Following this operation there was complete relief for two years and then abdominal distress began

and culminated in intestinal obstruction in six months. For this she was operated on by a physician in her home town. A few months later she came in again and I did a second operation, separating all adhesions. Complete relief followed, but she returned in another year with the same condition. In all, five subsequent operations have been necessary. In one, 18 inches of bowel was removed. Amniotic fluid has been introduced to prevent adhesions and in the second to the last operation a switching was made around a bad area which was thus rendered silent. This gave relief for nearly three years. She gained as much as 27 pounds (12 Kg.) but returned recently with great loss of weight, marked indigestion and great pain. The abdomen was opened and the silent area was found to be functioning somewhat. Dense adhesions to the abdominal wall were separated. She is improving rapidly and has returned to her home.

Medical Care for the American People

DR R. G. LFLAND, Chicago. Medicine has constantly adhered to certain scientific and ethical standards, self imposed and designed to protect the welfare of the people. It is in the spirit of warning against the methods of medical practice that will destroy the quality of medical care that medicine has repeatedly recorded its opposition to all forms of sickness insurance and state medicine proposed, controlled, operated and subsidized by the state. All over this country in counties and in cities, experiments in relationship to hospitals and to industry are now going on for saving against the costs of hospital care and against the costs of sickness. The medical profession has never objected to such experiments provided they are carried out in such a manner as to protect both the patient and his doctor against exploitation and to maintain the quality of medical service. Physicians have recognized the necessity of giving to all the sick the right kind of medical care. They have always done it and there is no reason to believe that they will fail to do their duty and to maintain their ideals in the future.

Pneumothorax Treatment of Lobar Pneumonia

DR JOHN J. HAMMOND, St. Louis. Of ten cases of lobar pneumonia, one terminated fatally. One case presented crises definitely associated with the pneumothorax. Symptomatic relief was obtained in practically 100 per cent as far as pain was concerned, and in seven of the ten cases in regard to dyspnea. The one death reported was not thought to be related to the injection of air as it followed this by twelve days and roentgenograms taken in the interim showed what was apparent improvement in the chest. The only complication or sequela noted was pleural effusion, and this was present in about 60 per cent of the cases, only one requiring tapping and none going on to suppuration. The general appearance of comfort following the injection of air was almost 100 per cent. Some of the patients requested further injections because of the marked relief of pain they experienced. I believe that the procedure has a place in the treatment of unilateral cases in conjunction with and not to the exclusion of other forms of therapy. In this series, pneumothorax was the only form of therapy employed other than symptomatic treatment. The use of serums and oxygen tents was out of the question, owing to their expense and to the fact that the City Hospital budget did not include these valuable therapeutic measures.

Diagnosis and Nonsurgical Treatment of Bronchiectasis

DR SAMUEL H. SNIDER, Kansas City, Mo. Probably one of the chief causes of bronchiectasis is an inherent weakness in the bronchial tree. Other factors are age, repeated respiratory infections with accumulation of secretions in the lower bronchial tree, putrefaction and fermentation of retained secretion, loss of ciliary action in the bronchial tree, and childhood type tuberculosis. The chief of these factors is repeated infections of the lower respiratory tract, often resulting from chronic or recurrent nasal sinus infection. The symptoms of bronchiectasis are often difficult to distinguish from those of simple bronchorrhoea. The picture is one of cough with bouts of profuse expectoration. In advanced bronchiectasis the pus may be very fetid and there are likely to be bouts of fever. Hemoptysis occasionally occurs in bronchiectasis. The physical signs are usually found in the lower part of the chest while those of tuberculosis are usually restricted to the upper part. Often considerable bronchiectasis exists without physical signs. Roentgenograms are invaluable

in confirming the diagnosis, and injections of iodized oil may be necessary to make the diagnosis clear. Iodized oil should be used with extreme caution when tuberculosis may exist. Repeated sputum examinations for tubercle bacilli should be made. The organisms usually found in bronchiectatic sputum are pneumococci, streptococci, *Bacillus fusiformis* and *Spirillum actinotum*. For treatment, the dilated bronchial tree may be regarded as a bottle with its mouth upward. The first objective is to dilate the bronchial tree, thus relieving the obstruction to drainage. This may be done with fumes of menthol or camphor or with epinephrine or ephedrine. Sometimes the bronchoscope becomes necessary. The second principle of treatment is to make the secretion less viscid. This is done with large doses of ammonium chloride or potassium iodide. The third principle is to invert the bottle, that is, give the patient the proper posture for drainage. Surgical treatment is reserved for those cases which have reached a stage at which medical treatment will not accomplish the desired relief.

Treatment of Diseases of Nasal Sinuses in Young Children

DR L. W. DEAN, St. Louis. The nasal sinuses in infants and young children are very precocious. It is most important in every case treated to know whether or not a given sinus is present and if present whether, on an anatomic basis, it has clinical significance. The most valuable information to be derived from a roentgenogram is the size of the various sinuses. The difficulty of differentiating between allergic and purulent sinusitis can best be solved by a careful clinical study and a cytologic investigation of the nasal discharge. Most infections of the nasal sinuses are due to allergic or nutritional disturbances. Occasionally a very virulent organism affects the sinuses in a normal child. In the laboratory it has been shown that nasal sinusitis can be experimentally produced by certain deficient diets. These things form the basis for treatment of uncomplicated purulent nasal sinus conditions in this class of cases. The essential thing in the treatment of acute purulent nasal sinusitis in infants and young children is bed rest, diet, the use of weak solutions of vasoconstrictors and some mild antiseptic in the nose. Chronic nasal infections without systemic complications are treated by eliminating allergic factors, removing infected lymphoid tissue from the pharynx, correcting conditions blocking the ostia of the sinuses, hygiene and outdoor play, an abundance of sunlight, and nutritional and vaccine therapy. When there is a systemic condition that demands rapid control of the infection, simple intranasal drainage operations may be indicated.

Treatment of Chronic Arthritis

DR R. A. KINSELLA, St. Louis. Of the two chief forms of arthritis with which the clinic is concerned, the rheumatoid type is characterized by its occurrence at an earlier age, the multiplicity of articular involvement and the predilection for small joints while avoiding the terminal joints of the fingers. Pain and swelling, stiffness and weakness are the common symptoms. The degenerative type can be visualized in the robust, often obese subject past middle age. This type exhibits predilection for the larger joints which are usually the chief weight-bearing joints. Redness and swelling are not common but when present usually have a monarticular arrangement and may represent focal infection. The treatment of the first type is unsatisfactory though important and useful. The treatment of the second type is successful. The treatment of the first type includes a utilization of all the measures available in physical therapy and orthopedic adjustment. In the treatment of degenerative arthritis the contribution of the orthopedist is most important, and this often begins with proper support of the arches of the feet. When evidence of inflammation exists it is usually not difficult to discover an actively inflamed area in the body the treatment of which is beneficial to the condition in the joint. The patient with rheumatoid arthritis continues to visit the clinic, the patient with degenerative arthritis is frequently discharged after a few months.

Hereditary Blindness in Missouri

DR. HARVEY D. LAMB, St. Louis. Among the pupils attending the Missouri School for the Blind in St. Louis during the last twelve years 38 per cent lost their sight from hereditary disease.

which represents a considerable increase over previous periods. Since hereditary disorders in the same individual are prone to appear in multiples, most of these pupils with hereditary blindness are mentally deficient. The presence of the latter condition increases the difficulty of their education to a tremendous degree. The inevitable procedure for the prevention of all hereditary disease must be sterilization. Simple tables were made listing the number of the pupils at the state school for the blind for each cause of hereditary disease of the eyes, as to vision for each such cause of blindness the percentage of hereditary blindness for each three year period from 1905, and the amount of hereditary blindness from communities of different sizes in Missouri. These tables were based on the ocular examination of 692 pupils in attendance at the school during the last thirty years. Of this number 217, or 31 per cent, were blinded as the result of faulty heredity.

The Changing Practices in Infant Feeding

DR. FRANK C. NEFF, Kansas City, Mo. In recent years there has been a rapid increase in the number of commercial foods for infants. The physician's office is abundantly supplied with samples. Advertising of some has extended to the radio. Professional and lay advisers of young mothers seem to believe that artificial feeding is safe and more convenient than attempting to nurse. On the other hand, emphasis has recently been placed on the fact that breast-fed infants have fewer infections. Careful methods of measuring the intake of breast milk in the hospital nursery show that most infants can be fed successfully on the breast if artificial food is kept away. Premature infants can now be cared for in an improved way with the air conditioned as to both temperature and humidity. Skilled nursing is necessary to avoid dangers such as overfeeding and aspiration of food. Breast milk and acidified evaporated milk have been found satisfactory if administered by special methods suited to the infant who may be too weak to nurse. So-called colic is not a feeding disturbance and calls for no change in formula. Quiet surroundings and sedatives are suggested. The wet nurse has become less expensive, since the milk is expressed, and there is no longer the problem of caring for an additional member in the home. A great change has occurred in the past few years through the use of concentrated milk formulas instead of excessively watery mixtures. Souring by various methods is a common procedure. Many types of sugar are available for addition to the formula with the tendency to use convenient and inexpensive types. Fresh milk is now successfully enriched in antirachitic vitamin, as is also canned milk. The evolution of feeding will not stop with present knowledge. Earlier weaning with addition of semisolid foods has advanced to a degree unbelievable a few years ago. While the feeding of infants has been greatly simplified, there has been much other improvement in this field of dietetics and thereby in infant welfare.

The Preliminary Stage of Labor

DR. BUFORD G. HAMILTON, Kansas City, Mo. One of the frequent questions asked by the expectant mother is "How shall I know when I am in labor?" This is not easy to answer. With a patient in suspected labor when I have seen the patient and made the usual examination I frequently cannot be certain that she is in labor. There may be pain with changes in the station and the condition of the cervix but there may not be continuous and progressive dilatation of the cervix. Many of my patients have a period in which little progress is made. It is this period in which the patient has pain with limited progress that I have designated as the preliminary stage of labor. I have attempted in office and hospital records to keep data on the duration of labor. Invariably my associate or intern has asked "When shall I say labor started or when would you say was the beginning of the first stage of labor?" I have asked the same question of interns from the many medical schools over the United States and with few exceptions different answers have been given. I am led to conclude that mechanical intervention, such as bags rupturing the membrane or giving castor oil and quinine, is contraindicated in this period. In each patient the judicious use of sedatives and waiting determines the successful outcome. I also believe important the education of patients in the antepartum period in the fact that such conditions are seen and that this period is often a part of the

picture of childbearing. The work of Calkins in estimating the force of pain and the character of the cervix is important in determining whether a patient is in labor. When continuous or progressive dilatation of the cervix can be determined, I should say that true labor has begun.

Physical Factors in Development of the Psychoses

DR. G. WILSE ROBINSON, Kansas City, Mo. The author emphasizes that all psychoses have a physical basis. So long as the brain functions in its normal manner, the mind manifests itself in its normal manner. Disordered brain activity in the majority of the psychoses is due to anatomic alteration of brain structure through disease of the brain, neoplasm developing within the skull, or trauma, or through intoxication by drugs, metals or alcohol.

Pernicious Anemia

DR. GEORGE E. KNAPPENBERGER, Kansas City, Mo. Pernicious anemia affects the blood-forming organs, the digestive tract and the nervous system. Achylia gastrica is the earliest and most constant sign of the disease. It is a deficiency disease, i. e., a lack of a specific factor present in normal gastric juice produced in the acid glands in the pyloric region through an enzyme reaction between the specific factor and some unknown factor in the normal diet. It is then stored in the liver and utilized as needed. The diagnosis is made on three cardinal signs: achylia gastrica, anemia and spinal cord degeneration, any two being sufficient for a diagnosis. The alcohol fractional test meal is sufficiently reliable for the clinical diagnosis of achylia. Histidine is unnecessary and at times dangerous. The anemia is usually of the macrocytic type. All the blood elements are reduced. The neurologic changes are degeneration of the lateral and posterior columns in the spinal cord, the signs varying from a loss of vibratory sense to ataxia or complete paralysis. The treatment is liver and stomach extract, orally or parenterally, the latter if the blood count is very low. The microcytic type needs iron also. Hydrochloric acid is useful to control diarrhea or flatulence but is not helpful as a routine. Refractory cases are encountered but large doses of liver will reduce this number. Blood transfusions are helpful only in the first two weeks or before the hematopoietic response of the liver has become apparent in the peripheral blood. The neurologic symptoms are often improved by treatment, but the physical signs are usually not altered. Failures in treatment can often be ascribed to insufficient treatment.

Complications of Appendicitis, with a Review of Six Hundred Cases

DR. JOHN WALKER STEWART, St. Louis. In 600 operative cases of appendicitis there was an average mortality of 13 1/2 per cent. There were 205 acute cases with seven deaths, a mortality of 3.419 per cent. Three of these patients were moribund on admission and operation. There were 250 sub-acute and chronic cases with no mortality. There were 135 appendectomies incidental to other operations, with a 2.222 per cent mortality. Fatal complications were: 1. Spreading peritonitis in twenty-eight cases, eighteen in the gangrenous type of appendicitis, nine in the acute purulent type, one in gangrenous Meckel's diverticulitis. Four cases were fatal. 2. Liver abscess with pyelophlebitis, present in one case in 600; the patient died. 3. Mesenteric thrombosis, present in one acute case, which was fatal. 4. Obstruction four months after appendiceal abscess drainage, on flare up of the appendix left in situ at the first operation with appendectomy and ileostomy. The mortality was 100 per cent. 5. Two cardiac deaths. Nonfatal complications were secondary peritoneal abscess in two cases, abscess of the abdominal wall in two cases, postoperative hernia in six cases, infections of the kidney pelvis in ten cases, thrombosis of one or both long saphenous veins with uneventful convalescence in four cases and blood in the stool postoperatively in five cases, one in an intussusception case in which the appendix had been strangulated and gangrenous. These 600 patients were operated on by the same operator in ten different hospitals. The technique and postoperative treatment were the same. The low proportion of complications was attributed to the use of gas anesthesia, prone position in drainage cases, free administration of intravenous fluids, withholding of food until subsidence of flatulence, and adequate use of narcotics in the first forty-eight hours after operation.

Schüller-Christian's Disease

DR. JOSEPH DAUKSIS, Excelsior Springs, Mo. In a review of the literature since 1931, a total of 123 cases conforming to the symptom complex of Schüller-Christian's disease have been found. A new case, the one hundred and twenty-fourth, is reported. A white man, aged 37, seen Nov 17, 1934, complained of constant headache and of a buzzing in his head following an injury about three months prior. History revealed symptoms of diabetes insipidus dating back to 1918. Soft spots in the top of the head had been present for about ten years. Examination showed a mildly prominent right eye, bony defects in the skull and a mild diabetes insipidus. Roentgen examination confirmed the presence of the skull defects and also showed a sella turcica that was shallow, with absent anterior clinoid processes. The blood cholesterol was increased to 235 mg per hundred cubic centimeters. The patient was referred to the radiologist for roentgen therapy. Analysis of the group of cases did not show any definite relationship to trauma and infection. Race and geographic distribution played no part and there was no familial tendency. The male sex was found more susceptible in the ratio of 2:1, and the age incidence was the greatest in the second, third and fourth years, though adult cases were not uncommon. The mortality of the group was 24 per cent. An increased blood cholesterol was reported in twenty-seven of thirty-nine cases. Defects of bones of the skull were present in 72 per cent, diabetes insipidus in 58 per cent, skeletal involvement excluding the skull in 48 per cent, exophthalmos in 44 per cent, skin lesions in 35 per cent, endocrine disturbances in 20 per cent, gingivitis and falling teeth in 18 per cent, and visceral involvement in about 10 per cent. Treatment has been of three varieties: dietary, glandular and roentgen therapy. The most promising results have been obtained with roentgen therapy.

Encephalitis Cases Causing Confusion in Diagnosis During the St. Louis Epidemic of 1933

DR. G. O. BROWN, St. Louis. Between July 1 and Nov 1, 1933, 129 typical cases of encephalitis were treated at Firmin Desloge Hospital in St. Louis. In the same period twenty additional cases were referred to this institution with a provisional diagnosis of encephalitis. The more careful study of these cases either established an entirely different diagnosis or at least rendered the original diagnosis doubtful. Since most of these cases had a preliminary examination by physicians who were seeing daily large numbers of true cases of encephalitis, it is obvious that the clinical picture must at least have had a strong resemblance to that of encephalitis. The most common conditions causing confusion were malaria and typhoid, especially when these were accompanied by marked cerebral symptoms. It is important to note that in some cases of these infections spinal fluid examinations revealed changes similar to those of encephalitis. The finding of malaria parasites and the response to quinine established the diagnosis of malaria. The bacteriologic observations and subsequent course served to differentiate typhoid. Tuberculous meningitis was differentiated by the low spinal fluid sugar and subsequently by a positive guinea-pig inoculation. Streptococcal meningitis yielded the causative organism in the spinal fluid in direct smear and also presented a much higher cell count than was noted in any case of encephalitis. Syphilis of the central nervous system was a confusing factor in several cases. Cerebral arteriosclerosis, alcoholism, epilepsy, pneumonia, ulcerative colitis and liver abscess caused confusion in other cases. The most important single laboratory examination in the differential diagnosis is undoubtedly the careful study of the cerebrospinal fluid. For study of doubtful cases during convalescence the virus neutralization test is of great value in definitely establishing the type of encephalitis present. Use of this test in some cases in this group demonstrates its clinical applicability.

Clinical Manifestations of Anorectal Disease

DR. GEORGE H. THIELE, Kansas City, Mo. Anorectal examination is often neglected because of failure either to elicit symptoms referable to the anorectum or to recognize the relationship between the symptoms and anorectal disease. It is felt therefore, that a discussion of the clinical manifestations of rectal disease may provide an impetus for more frequent anorectal examination as a general diagnostic procedure. Nervous,

gastro-intestinal, genito-urinary and rheumatic symptoms if looked for, are to be found in most patients with anorectal disease. These symptoms are often not associated with rectal disease by the patient, and, not associating them, he often does not regard such symptoms as slight itching or irritation of the anus as of sufficient importance to warrant mentioning to his physician. Such symptoms were found in seventy of a group of 225 consecutive cases from private practice. One feels that the incidence would be much higher in clinic cases, in which rectal examination is easily available and done more as a routine procedure. These symptoms fall quite naturally into four groups: gastro-intestinal, nervous, genito-urinary and rheumatic. They are produced either as nervous reflexes or as manifestations of focal anorectal infection. Symptoms occurred 227 times in seventy patients, 143 (63 per cent) were cured, 57 (25 per cent) were improved, 12 (5 per cent) were unimproved and 15 (6 per cent) were not recorded in the progress records of the patients. When such symptoms are encountered, a thorough anorectal examination should be made. Digital examination alone is not sufficient, as many of the lesions in the anorectum are not palpable.

An Institutional Outbreak of Shiga Dysentery

DR. T. S. LAPP, Fulton, Mo. In the institutional outbreak of Shiga dysentery, comprising ten cases, the Shiga bacillus from one case was identified by its non-acid forming properties in mannite and its agglutination by Shiga agglutinating serum. A patient working in the dining room in the ward in which the epidemic occurred was thought to be a carrier of the Shiga bacillus. This was determined by his serum agglutinating a stock culture of Shiga bacilli in a titer of 1:100. Autopsy in one case in which death occurred during the acute phase of the disease revealed an acute catarrhal inflammation of the colon and ileum with ulcerations of the sigmoid. The regional mesenteric lymph glands were enlarged. Autopsy in a second case, in which death occurred a year after recovery, revealed that the colon was bound down throughout its entire course by bands of adhesions, which were more pronounced at the hepatic and splenic flexures. There was a wide variation noted in the symptoms presented in these cases. The majority occurred in patients over 50 years of age. Some were extremely toxic and had large quantities of blood in the stools, others were of a milder nature and were ill only a few days. There were three deaths, giving a mortality rate of 30 per cent. Isolation precautions were observed in all cases. They were treated with polyvalent antidyenteric serum. Symptomatic and supportive treatment was given as indicated.

Ocular Tuberculosis

DR. C. S. O'BRIEN, Iowa City. Tuberculosis of the eye, especially of the uveal tract is common, although it is frequently unrecognized. Frequently focal infection in the teeth, tonsils, sinuses or other structures is regarded as a cause of an ocular inflammation that really has its origin in a latent or arrested tuberculous focus. Tuberculosis of the eye is usually secondary to a latent primary focus in the chest, glands, bones or joints. The inflammation in the eye may be allergic in nature and arise as a result of hypersensitivity to tuberculinoprotein, which is disseminated from the primary focus, or it may be the result of actual invasion by tubercle bacilli that have been carried from the primary focus through the blood stream. Diagnosis is often difficult, since this type of inflammation occurs in an apparently healthy person. The latent primary focus is rarely recognizable on physical examination, and it is only by roentgenograms that evidence of old calcified primary lesions is found. The ocular inflammation is usually insidious, pain and congestion are mild or absent, there is a tendency toward slow progression, and relapses are frequent. In uveal tuberculosis, other parts of the eye often become involved. Tuberculin is a useful diagnostic agent, but it must be used carefully and in an intelligent manner. Syphilis, focal infections, sympathetic ophthalmia, glioma and rare conditions such as ophthalmia nodosa are to be considered in the differential diagnosis. Treatment is similar to that for tuberculosis in any situation, i. e., removal of foci of infection, proper diet, ultraviolet rays or sunshine, fresh air, and periodic rest. Tuberculin is often of apparent benefit; it is to be administered in small doses over a long period.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

58:355-540 (May 15) 1935 Partial Index

Studies on the Main Posterior Lymph Channels of the Abdomen and Their Connections with Lymphatics of Genito-Urinary System. Alice E. Parker. Denver.—p. 409.

Reaction of Omental Tissues to Trypan Blue Injected Intraperitoneally with Especial Reference to Interrelationships Between Cell Types. J. S. Latta and D. I. Rutledge. Omaha.—p. 481.

American Journal of Clinical Pathology, Baltimore

5:173-260 (May) 1935

Use in Wassermann Reaction of Uniform and Stable Dehydrated Complement. H. Eagle, Philadelphia. H. Strauss and R. Steiner.—p. 173.

Pathologic Changes Resulting from Excess and Deficient Secretion of Ductless Glands. A. M. Young. Cleveland.—p. 180.

*Unfavorable Reactions Due to Antirabic Treatment. Three Cases. F. C. Hodges. Huntington. W. Va.—p. 211.

Withdrawal Aleukocytosis in Experimental Peritonitis. C. A. Pons. J. M. Gannon and W. P. Belk. Ardmore, Pa.—p. 225.

Initial Lesion in Treponematosis Framboesiana. C. S. Butler. Brooklyn.—p. 231.

*Relationship Between Oxyuriasis and Appendicitis. Margaret Warwick. Buffalo.—p. 238.

Familial Shift to Left of Granular Leukocytes. R. F. Peterson, Butte Mont.—p. 249.

Adapter for Sheard Sanford Photometer. A. S. Giordano. South Bend Ind.—p. 253.

Reactions Due to Antirabic Treatment—Hodges states that paralytic accidents develop in about 0.0028 per cent of persons who receive the antirabic inoculations. These are ascending paralysis of the Landry type, with a mortality of 30 per cent, dorsolumbar myelitis, with a mortality of 5 per cent, and monosymptomatic paralyses (facial palsy, an arm or leg or a single muscle, sphincter disturbance) with no mortality. These symptoms are manifest during or soon after treatment, usually between the eleventh and twentieth day, whereas rabies usually begins from the fortieth to the sixtieth day. Possibilities of antirabic accidents should be borne in mind when giving the treatments. Precautions to be observed are to keep the patient as near rest as possible during the treatment and, on the appearance of the paralytic accident, to stop the treatments at once. Whether to resume them or not depends on the relative dangers of the accident and the risk of the development of rabies. Three cases of paralytic accident are discussed, two of which resulted in death. The first patient was a man with an ascending paralysis of the Landry type, finally involving the medulla on the thirteenth day of treatment by antirabic inoculations. He was not bitten by a rabid animal, only the saliva coming in contact with the unbroken skin of his hands. The second patient was a boy, aged 4, who developed meningo-encephalitis beginning six weeks after treatment and who died twenty-one weeks after the bite of a rabid dog. The duration of the illness was three months. There was no antecedent acute illness which may have caused encephalitis. The third patient was a male laborer, whose reaction was of the dorsolumbar myelitis type.

Oxyuriasis and Appendicitis—Warwick reports that oxyuriasis was found in 19 per cent of 2,344 appendixes examined. No distinguishing symptoms were caused by the parasite which differentiated its presence in the appendix from inflammation of that organ. It seems probable that the presence of the parasites in empty lumens may cause painful contractions of the muscular wall which may simulate the symptoms of appendicitis. The average age of the patients was 18 and varied from 6 to 34 years with 60 per cent more than 16 years of age. Females were affected in 93 per cent of the cases. Oxyuriasis was rarely

associated with a temperature elevated above 100 F. A leukocytosis was present in 42 per cent of the nineteen cases in which a count was done, but there was no appreciable eosinophilia. No characteristic lesions that could be attributed to the presence of the parasites were found in any of these cases. After removal of the organ the parasites may penetrate the wall of the appendix, but apparently not before.

*Eosinophilia in Scarlet Fever. II. General Considerations. S. Friedman. Boston.—p. 1256.

Eruptive Fever with Stomatitis and Ophthalmia—Ginandes reports a case of an eruptive fever with cutaneous, buccal and ocular lesions similar to those of the two cases described by Stevens and Johnson (*Am J Dis Child* 24:526 [Dec.] 1922) as instances of a new clinical entity. Similar cases described by Rutherford and by Wheeler are discussed. The literature is reviewed, and the striking resemblance of these cases to certain others reported as instances of atypical erythema exudativum multiforme (Hebra) is pointed out. The suggestion is made that all these strikingly similar cases be considered as belonging to one group. The exact classification and nomenclature of such a group are left open for further study and investigation. If the term 'erythema exudativum multiforme' is to be retained, it is suggested that the name "Stevens-Johnson" be substituted for "Hebra" in order to emphasize the unusual features of this disease.

Test for Infectious Mononucleosis—Davidsohn says that finding an elevated titer of agglutinins for sheep red blood cells in a person who has not recently received an injection of horse serum and who presents a clinical and a hematologic picture suggestive of infectious mononucleosis indicates with a high degree of probability the presence of infectious mononucleosis. The test also offers a reliable means of a specific diagnosis that has not been available heretofore. The test will be valuable in differential diagnosis, particularly for the exclusion of early cases of acute leukemia. Such errors in differentiation have been made. There are cases of infectious mononucleosis with abdominal symptoms which resemble closely an attack of acute appendicitis. The author's case was of this nature. The test may eliminate the need for operative intervention if such a possibility is kept in mind. It seems probable from certain reports in the literature that cases of infectious mononucleosis with severe anginal lesions are mistaken for cases of diphtheria, and the patients are treated for that disease. In all these cases the diagnosis of infectious mononucleosis by means of a positive serologic test will enable one to eliminate unnecessary thera-

peutic procedures. A technic of agglutination is suggested which is preferable to the older method because it permits the reading of results at the end of two hours and is more sensitive.

Eosinophilia in Scarlet Fever—Friedman has analyzed the results in 100 cases of scarlet fever. The cases were divided according to the degree of intensity of the exanthem on the patient's admission. Type of rash: very mild, grade 1, mild, grade 2, moderate, grade 3, bright, grade 4, and intense, grade 5. The maximal eosinophil count attained in each case was compared with the degree of exanthem. The patients with the more intense rashes did not show the highest eosinophil counts. If anything, the counts were distinctly lower. Thus, Br's conclusion is erroneous and cannot be used as evidence in favor of Naegeli's theory of the nature of the eosinophilia in scarlet fever. However, the greatest objection to attributing the eosinophilia either to allergy or to the exanthem arises from the presence of the secondary eosinophilia. The author believes that the eosinophilia in scarlet fever is a manifestation of the formation of antitoxin in the body during the course of the disease. The primary rise begins to be evident when the condition of the patient is obviously ameliorated, in other words when sufficient antitoxin has been formed to combat successfully the toxin of the organism of scarlet fever. The free antitoxin in the blood exerts a chemotaxis for eosinophils, thus producing eosinophilia in the circulating blood.

- ***Typhoid Fever Among Household Contacts with Especial Reference to Vaccination**. G. H. Ramsey, Albany, N. Y.—p. 665.

Typhoid Among Household Contacts—Ramsey studied the incidence of typhoid among household contacts of sporadic cases. The secondary attack rate among susceptible contacts of all ages was found to be 7.03 per cent. Children were more severely affected than adults, men and women were attacked with almost equal frequency. An apparent reduction of 33 per cent in secondary case incidence occurred in families in which the primary patient was removed to a hospital as compared with families in which the primary patient remained at home. The secondary attack rate among household contacts living in places of less than 10,000 population was three times higher than the rate among contacts in places of 10,000 or more inhabitants. Among household contacts who used well water and lived on premises with cesspools or privies the secondary attack rate was three times higher than the rate among contacts served by public water supplies and sewerage systems. Both among household contacts of primary patients remaining at home and primary patients sent to the hospital, reductions of 75 per cent from the expected secondary case incidence were observed among contacts who had received three doses of vaccine subsequent to the onset of the primary case.

- Oculoglandular Tularemia**. II. G. Merrill and L. W. Oaks, Provo, Utah.—p. 453.

Epinephrine Bitartrate—In addition to its action of lowering tension in chronic simple glaucoma, Cordes and Harrington have found epinephrine bitartrate useful as a mydriatic for: (1) examination of the fundi in eyes with high normal tension, (2) examination of the fundi in glaucomatous eyes which are under the influence of a miotic, (3) powerfully dilating the pupil with the separation of posterior synechia in cases of old or neglected iritis and (4) dilating the pupil during the operation for congenital, soft, membranous or traumatic cataract. The marked vasoconstrictive action of the drug, which exceeds that of epinephrine, makes it an ideal hemostatic in the removal of chalazias, in cyclodialysis and in the operation for retinal detachment, in which a dry field is essential.

Röntgen Carcinoma of Both Hands—Ochsner has seen twenty roentgen carcinomas: one of the neck, the result of roentgen therapy for tuberculous glands; one of the face, following roentgen treatment of an extensive lupus; one following a roentgen burn of the abdominal parietes; and seventeen of the hands of radiologists. Fourteen have succumbed to generalized cancer.

cachexia or hemorrhage due to extension of the process into a large vessel. Four are living and apparently well after excision, for periods varying from four to twenty nine years. Two are still under treatment. In cases in which there is a thick layer of subcutaneous tissue, complete excision whenever possible is the procedure of choice. The three, in which this operation was possible, have apparently recovered permanently. In only one instance of amputation of fingers or hands has he seen what appears as a permanent cure. This was in a patient in whom only one finger was involved. The others of this type have ultimately succumbed from recurrences, a number of them after multiple amputations. The patient, whose history he reports, would he believes, have had little chance of complete recovery except by amputation of both upper extremities above the wrists, and even then, in view of past experiences in like conditions, the outcome would have been extremely doubtful. Instead with the treatment he received (colloidal gold with tincture of iodine), he has had nearly normal use of his hands, no discomfort and at least a fair prospect of ultimate complete recovery.

Cerebral Lesions in Mentally Defective Children.—Bagley discusses the importance of accurate diagnosis of the type of cerebral lesion present in mentally defective children from a postmortem study of eight brains of such patients aged from 4 months to 34 years. Whether the lesion is congenital or acquired is of great importance. In the former one should attempt to determine whether there is a true hereditary condition or whether the defect was acquired during intra-uterine life. Since the lesion in many of the postnatal cases is acquired at birth, it is often difficult to differentiate them from congenital cases. However, in the majority of the acquired cases there is a sudden onset of symptoms which, when coupled with the history of an etiologic factor makes differentiation possible. The etiologic causes in hereditary cases are syphilis, chronic alcoholism, consanguinity and familial mental deficiency. Inflammation and trauma are by far the most important causes in the acquired cases, whether they be prenatal or postnatal. Of the cases included in this report cerebral inflammation during infancy was the etiologic factor in three. Two died within a few months, the third lived to the age of 34. In the fourth case the child had a hemorrhage at birth and was ill until the seventh month when it died. The fifth patient had an injury in the posterior part of the longitudinal sinus during birth with a moderate amount of bleeding over the cortex and stenosis of the longitudinal sinus at the site of the injury. The sixth and seventh patients had amaurotic family idiocy and represent the hereditary lesions. The last patient had hydrocephalus with an almost complete absence of the cerebral cortex secondary to occlusion of the aqueduct of Sylvius. This case probably represents an acquired intra-uterine inflammatory lesion. The possibility of surgery must be recognized in some cases, and likewise the surgical limitations must be realized and adhered to, for these unfortunate patients have often been the subject of unfair treatment at the hands of the overzealous surgeon. Blood, whether it is diffused in the cerebrospinal fluid or in the form of a clot which produces symptoms should be removed at the earliest possible moment by lumbar puncture or craniotomy. Patients in whom the blood has not been removed early may be helped by operation if it is undertaken before the secondary meningeal and cerebral changes are far advanced. Surgery has nothing to offer in the nonsuppurative cerebral inflammatory conditions.

Shotgun Wounds of the Abdomen.—Willis urges that, in scattered abdominal shotgun wounds all points of entrance be surgically cleaned and properly dressed and recommends the following prophylactic doses of antitetanic and perfringens serum, absolute rest in bed, sufficient opiate to depress respiration to 12 or 14 per minute, nothing by mouth, phlebotomy of 1,000 cc. of 5 per cent dextrose three times a day or Herndon's continuous phlebotomy, repeating the antitetanic serum on the fifth day and continuing oral starvation for from six to ten days, depending on the condition of the patient and the size of shot. Should more fluid be desirable, hypodermoclysis or intravenous injection can be used. In none of his surviving patients did a serious hemorrhage or abscess develop but these may occur therefore the patient should be carefully watched

and the abdomen examined from time to time. Enemas should not be given since fluid may be forced through perforations. The treatment of massive wounds must largely remain an immediate surgical procedure since in this type large holes are torn in the intestine, sometimes with complete severance. After operation these patients may be treated along the same lines as those with scattered wounds. The author has done experimental work on twenty-five dogs. From his experimental and clinical experience he is convinced that patients with scattered shotgun wounds should rarely be operated on, and then only for drainage of abscess or in the hope of controlling active hemorrhage.

Intussusception Due to Familial Tumors of Small Intestine.—Haggard and Floyd believe that the phenomenon of familial intussusception is well illustrated in the case that they report. The father had four operations for obstruction, three due to neoplasms, the last being a malignant degeneration of a polyp in the colon. His daughter had two operations for obstruction due to benign growths, while the son (the case reported) had three resections for intussusception from polyps, making a total of nine resections in three members of the same family seven of which were for benign neoplasms of the small intestine, one for obstruction by band and one for carcinoma. Intussusception in adults is chiefly and in children often caused by neoplasms. When an intussusception is reduced, the segment should be carefully examined for an intraluminal causative tumor and others should be looked for. When operation is done for colic-like abdominal pain and the condition of the appendix, gallbladder or pelvic or other organs does not explain the symptoms, intestinal tumors should be looked for.

Cardiac Pain.—Katz and his associates confirm the observation of previous workers that occlusion of the coronary vessels and the surrounding tissue in the unanesthetized dog gives rise to a response resembling an anginal attack. The response from this procedure is similar to that obtained on compressing a superficial somatic sensory nerve, save for the inability of the animal to locate the site of irritation. The authors' results show that this response is due not to the occlusion of the coronary artery but to stimulation of afferent fibers located in the nerve plexus surrounding the vessels. The evidence for this is: 1. Occlusion of a carefully isolated strip of the coronary artery caused no response, but a definite response was obtained when the undissected coronary vessels above and below this point were compressed. 2. Destruction of the nerve plexus with phenol and alcohol abolished the response to compression, but the response was still positive when a region above the phenolized area was stimulated. 3. Complete preliminary occlusion of the carefully isolated coronary artery did not prevent a positive response to compression above or below this point. 4. Pericardial tamponade following bleeding from a ruptured coronary artery caused syncope, but no "anginal"

response Positive responses occur only when the region about the coronary vessels is compressed The rest of the myocardium and epicardium is insensitive to stimulation by pressure Ischemia of the myocardium is one of many mechanisms operating on the nerve endings and nerve fibers which may give rise to anginal attacks

Mushroom Poisoning—Vander Veer and Farley state that nearly all the severe cases of mushroom poisoning (mycetismus) in this country result from the ingestion of one of the varieties of the genus *Amanita* These cases may be divided into 'rapid' and 'delayed' types The rapid type of poisoning occurs within from one to three hours after ingestion of fungi of the *Amanita muscaria* group, and is characterized by excessive salivation, perspiration and lacrimation Nausea vomiting, severe abdominal pains and diarrhea occur The pupils are contracted Convulsions and coma are seen in the severe cases The mortality is low and the patients respond well to the proper treatment The delayed type of mycetismus results from the ingestion of mushrooms belonging to the *Amanita phalloides* group The onset is delayed until from six to fifteen hours or more after ingestion of the fungi Abdominal pains are severe, and nausea and vomiting may be extreme Diarrhea is nearly always present The patients are prostrated from the onset Jaundice nearly always occurs and renal damage is frequent Symptoms resulting from damage to the central nervous system are usually present The mortality in this type of poisoning is at least 50 per cent Extremely ill patients, even those with marked nervous symptoms deep jaundice and evidence of renal damage, may recover completely Care should be taken to keep the patients at complete rest until recovery is assured In the rapid type of mycetismus the early onset of vomiting and diarrhea is of value in removing the poisonous fungi from the gastro-intestinal tract No attempt should be made to alleviate these symptoms If the stomach is not completely emptied, gastric lavage should be carried out with saline solution or an emetic should be given A saline purge may be left in the stomach after it has been irrigated, or the cathartic may be administered by mouth to aid in emptying the lower portion of the gastro-intestinal tract Atropine sulphate should be given at once hypodermically in all cases in which there is evidence of the action of muscarin In the patient who shows symptoms of collapse caffeine strychnine and epinephrine should be given in full doses in order to tide him over the acute stage, after which recovery occurs rapidly The late onset of symptoms in the delayed type of mycetismus allows the fungi to be well down the gastro-intestinal tract before symptoms appear Emetics and gastric lavage should be employed at once to make certain that the stomach is empty Thorough purging is especially important to empty the ileum and colon quickly High enemas may be given All the patients who are known to have eaten the same fungi, but in whom symptoms have not appeared, should undergo emptying of the gastro-intestinal tract at once Relapse with a fatal issue is not uncommon in patients who have been ill several days and who are apparently improving Opiates are usually indicated and should be given hypodermically for the relief of the severe abdominal pains and delirium and in order to induce sleep A liquid diet with high carbohydrate content should be given when possible because of the hepatic and renal damage Intravenous administration of dextrose in physiologic solution of sodium chloride is of value for patients with marked and persisting gastro-intestinal symptoms A 10 per cent dextrose solution should be used and from 500 to 1,000 cc given every six to eight hours Physiologic solution of sodium chloride given subcutaneously or tap water rectally may prove of value by increasing the intake of fluids The presence of shock and circulatory collapse should be combated by the usual methods The external application of heat and the use of caffeine, strychnine and epinephrine (in full dosage) may be indicated The use of an antitoxin serum has been advocated in this type of poisoning and has been used in France and Germany There is no similar antitoxin available in this country

Habitual Hyperthermia—Reimann failed to find any organic basis for low grade fever known to have existed in four patients for at least twenty one six, seven and fourteen years respectively Analysis of the temperature records of

these patients indicates that in each the range fell within the limits of normal The temperature in certain normal persons may be regulated slightly above the usually accepted normal level and in some persons of a neurotic nature the elevated temperature is one of the signs of their abnormal constitutional type together with other evidence of vasocardiac and nervous instability Persons of this nature are not rare The condition should be regarded as a neurosis or as habitual hyperthermia only after thorough and prolonged examination fails to reveal an organic basis There are no infallible criteria for determining a diagnosis Each case must be regarded individually Certain data helpful in establishing a diagnosis are discussed The picture must be considered as a whole, with especial emphasis on the constitutional type of the person, the nature of the symptoms and signs, the constancy of the temperature, the absence of evidence of infection or other organic disease the constancy of weight, the normal metabolism and the response to antipyretic and narcotic drugs

Abnormalities of Spinal Fluid in Treated Neurosyphilis—Goodman and Moore present a study of the incidence of clinical progression or relapse after prolonged treatment in 212 patients with neurosyphilis A comparison is made between two groups ninety-five patients for whom the reaction of the spinal fluid remained persistently positive and 117 for whom the positive reaction was reversed by treatment In the groups as a whole, clinical progression occurred in 22 per cent of the Wassermann fast patients and in only 7 per cent of those with reversed reactions Limiting the study to patients treated for two or more years, subsequent progression occurred in 12.5 per cent of the Wassermann fast group and in 4.8 per cent of the group with reversed reactions Progression or relapse is more common in patients with parenchymatous neurosyphilis (tabes and dementia paralytica) than in those with nonparenchymatous types of neuraxis involvement Even in a patient with apparently nonparenchymatous neurosyphilis the subsequent relapse, if one occurs, is likely to be similar to dementia paralytica Of thirty-one patients who received induced fever therapy (chiefly malaria) subsequent progression or relapse occurred in only two While there is a more definite relationship between the clinical outcome and the reaction of the spinal fluid in neurosyphilis than between the reversal or the fastness of the Wassermann reaction of the blood in various forms of late syphilis not involving the nervous system, a persistently positive reaction of the spinal fluid does not indicate the inevitability of subsequent progression or of relapse nor can the rate or completeness of reversal of the reaction be used as the sole guide to the optimal duration of treatment in cases of neurosyphilis

Pathology of Radium Burns—Lynch classifies the stages in the development of a radium burn into three main divisions 1 The stage of engorgement followed by an increase in the number of polymorphonuclear leukocytes and their migration to the surrounding tissue. Associated with this is an increase in the blood flow in this area 2 The stage of constriction of the vessels followed by edema of the endothelial lining injury to the vessels of the walls and thrombosis The flow of the blood at this stage is slow, the capillaries have become thrombosed or have been occluded owing to the edema of the walls and the larger arterioles and arteries are the only vessels that are functioning 3 As a direct result of the

second condition and a later injury to the larger vessels necrosis of the tissue, which takes place owing to the loss of blood supply

Influence of Middle Ear on Labyrinthine Pressure—

The studies of Kobrak show that changes in the pressure in the middle ear are transferred to the labyrinth. The smallest change in pressure that was necessary to produce a movement in the labyrinthine fluid in rabbits was approximately 0.3 cm of water. The changes of pressure in the middle ear that occur during life (swallowing, coughing, sneezing and Valsalva's experiment) are equal to or greater than those which were found to be necessary in order to cause a movement of the labyrinthine fluid. Extremely small changes in pressure in the middle ear do not produce changes in the acoustic reflex of the tensor tympani muscle. Greater changes in the pressure in the middle ear, either positive or negative, produce a decrease in the degree of the contraction. The resistance in the aqueductus cochleae may be dependent on the frequency of a periodic change in the pressure. The fluid of the inner ear can be displaced by the contraction of the intrinsic muscles of the ear. A tetanic contraction of the tensor tympani muscle caused by nicotine produces a strong movement of the labyrinthine fluid. Clinically, from the diagnostic standpoint, the author believes that diseases of the inner ear may be due not only to organic lesions in the labyrinth, as is assumed for the classic Ménière syndrome, or to changes in the blood supply (angiopathic Ménière syndrome) but also to alterations in the pressure in surrounding parts (middle ear, intracranial cavity). The symptoms seen in Krassing's experiments may be referred to the changes seen in the present experiments and to the development of the Ménière symptoms after inflation as instances of a "tympagogenic" Ménière disease, or "tympagogenic labyrinthopathy". It would be worth while to include these possibilities of disease of the labyrinth when making a differential diagnosis. Therapeutic results may be obtained by influencing the labyrinth from without by means of procedures carried on in the middle ear. This type of treatment has been tried. For instance, Krabowski treated patients with Ménière's disease by inserting a Siegle speculum in the outer ear. By means of movements of the whole ossicular chain he attacked the labyrinth and produced a favorable effect.

Chemical Nature of Hematopoietic Substance in Liver

—Dakin and West describe the preparation from commercial liver extract of products clinically active in causing remission in pernicious anemia. The method is based on the removal of much relatively inactive material by precipitation with

alcoholic calcium acetate, followed by precipitation of the active material with Reinecke acid. Subsequent purification is effected by salting out the active material with ammonium sulphate and later by the use of either magnesium sulphate, sodium chloride or flavianic acid. About 30 mg of the product caused a perceptible reticulocyte response in suitable pernicious anemia patients, while 80 mg has given a maximal response. Under suitable conditions, substantially the whole of the active material is precipitable by ammonium sulphate, since none could be recovered from the filtrate. Precipitation in the magnesium sulphate is quantitatively less complete. The yield of purified product approximates 1 per cent of the dry liver extract. The clinical activity of the product is readily abolished by exposure to cold 0.5 normal solution of sodium hydroxide and by boiling for one hour with 0.5 normal solution of sulphuric acid and also by salts of heavy metals. Exposure to alkali involves extensive racemization. On hydrolysis of the active material an aminohexose similar to glucosamine but not definitely identified as such, was obtained and lysine, arginine, glycine, leucine, hydroxyproline and aspartic acid were present in all the preparations obtained so far.

Van den Bergh Reaction in Icterus—In twenty-four full term infants, Elton examined 131 specimens of blood at frequent intervals during the first ten days of life to determine the character of the van den Bergh reaction by the ring test technique and to correlate blood bilirubin and hemoglobin changes during the course of icterus neonatorum. The positive van den Bergh reaction was found to occur in 36 per cent of all specimens during the second to the tenth day and to attain a maximal frequency of 55 per cent on the sixth day. Since the most complete studies reported in the literature on variations in erythrocyte counts and hemoglobin values in the new-born show that a relative or absolute polycythemia develops after birth and usually within the first two days of life, and since during the same period the bilirubin level is rapidly rising in the blood, the postulation of excessive blood destruction as the underlying cause of icterus neonatorum does not appear reasonable. Partial anoxemia induced by the patency of the ductus arteriosus and a disturbance of liver function induced by the patency of the ductus venosus Arantius provide rational explanations of the transient polycythemia and jaundice during the early neonatal period as two independent phenomena. No correlation has been found in the data derived from this investigation supporting the assumption that blood destruction is a factor of any appreciable significance in the etiology of icterus neonatorum. The levels of bilirubin and hemoglobin in the blood tend to rise and fall together, although at times they are

subject to erratic fluctuations. The patency and closure of the ductus venosus are presented as the logical factors in the etiology, intensity, duration and termination of this icterus.

Weight Reduction with High Protein Diets—Campbell has observed an average loss of weight of from 1½ to 6 pounds (0.5 to 3 Kg) per week in twenty-seven subjects having non-pathologic obesity during a period of from four to fifty weeks. The diets were of the high protein type containing approximately 2 Gm of protein per kilogram of ideal body weight. The caloric value of the diets was from 20 per cent above to 39 per cent below basal maintenance. However, most of the diets afforded a caloric value of about 20 per cent below basal requirements. The patients maintained excellent health, continued all their normal activities and had an increase of energy as the weight decreased. The large amount of lean meat and vegetables prevented the hunger of which most individuals complain during weight reduction on low protein diets. There were no changes in the kidney function or blood pressure during any period of the observation. Nitrogen balance was maintained at all times. The caloric expenditure afforded by the high protein diet in one case was 7 per cent above that of an isocaloric high carbohydrate diet.

Coronary Arteriosclerosis and Auricular Fibrillation.—

Brown made a study of all cases coming to necropsy during a period of twenty years that showed auricular fibrillation, exclusive of those with known rheumatic valvular disease. Particular attention was paid to the relation between this irregularity and disease of the coronary arteries. Hypertension was an etiologic factor in 79.3 per cent of the cases with permanent fibrillation and in 86.5 per cent of the cases with transient fibrillation. Significant disease of the coronary arteries, although fairly frequent among those with hypertension, was not common as the sole factor in the development of permanent auricular fibrillation. Angina pectoris and coronary thrombosis were comparatively rare in patients who had had auricular fibrillation. There was a group of nine cases classified as of undetermined etiology that did not present significant coronary artery disease or known previous hypertension. There were nine cases showing other forms of heart disease, such as pericarditis and unrecognized stenosis of one of the valves. Finally there were an additional fifteen instances of auricular fibrillation showing no disease of the heart, in five of which there was hyperthyroidism. Men predominated over women in a proportion of two to one and the ages ranged from 39 to 89 with the majority between the years 50 to 70. The heart weight was greater in the men and with permanent fibrillation than in the women or with transient fibrillation. Although congestive failure was the most common cause of death it is of interest that pulmonary infarction was quite frequent and renal insufficiency rare. Evidence is presented that marked peripheral sclerosis of itself need not be an indication that the coronary arteries are sclerosed or that the efficiency of the heart is in any way altered. This suggests that the term arteriosclerotic heart disease should be given up entirely or clarified in its expression.

Xanthomatosis Involving Bone—Smith presents the case histories and roentgen observations of two patients with Schüller-Christian's disease and one with a metastatic hypernephroma associated with xanthomatous changes. The latter exemplifies a condition not unusual but readily confused with bone tumors of simple xanthomatous nature much more benign and of much rarer occurrence. One of the Schüller-Christian cases presented a marked but temporary osteosclerosis surrounding one bone lesion the entire area being later filled with

normal bone. Both patients with Schüller-Christian's disease now appear clinically well, one spontaneously after extensive operative treatment and the other after radium therapy. The classification, roentgen studies, differential diagnosis and radiation therapy of the various xanthomatous lesions affecting bone are discussed and the literature is reviewed. The roentgen observations are often of greater importance in diagnosis than the histologic, particularly in Schüller-Christian's disease after the earlier stages.

Force of Gravity in Pneumothorax Cavity—Korol states that under normal conditions the lung is but slightly stretched by its own weight, largely because of atmospheric pressure holding the lungs against the parietal pleura in opposition to gravity. The lung is also protected from excessive stretching by the heart and abdominal viscera. After the induction of pneumothorax, the lung sinks toward the bottom of the pleural cavity by its own weight. In case of mediastinal or diaphragmatic adhesions, the heart and abdominal viscera exert traction on these adhesions, sometimes tearing them. The lung moves about freely in the pneumothorax cavity during changes of posture. In roentgenograms taken in the erect position the air bubble appears on the top of the lung producing an illusion of selective collapse, and in roentgenograms made in the knee-chest position the air readily shifts toward the diaphragmatic region in accordance with the laws of gravity and inertia. The weight of the lung may kink one or more of the lobar bronchi, producing massive atelectasis. If the bronchial lumen is but partly occluded there will result obstructive emphysema and enlargement of the cavities in the lung treated by pneumothorax.

Comparison of Effects of Beta Rays of Radium—Baker compared quantitatively the destructive effects of the beta rays of radium on *Bacillus coli*, *Staphylococcus aureus*, bacteriophage, filtrate of Rous sarcoma no. 1 tetanus toxin, *Bacillus anthracis* spores, hemolytic amoebocyte guinea-pig complement trypsin and lysozyme. The Rous sarcoma agent falls within the bacterial group as regards susceptibility to destruction by beta rays. On the other hand, tetanus toxin also falls within this range, so that it is obviously not possible to deduce that the Rous agent is a living organism. On the other hand the ferments so far examined are much more resistant to destruction than the most resistant organism tested (anthrax spores). Recent work by Northrup on the destruction of crystalline pepsin by beta rays has shown that the loss of activity parallels the disappearance of protein nitrogen from the solution. This together with its high resistance to destruction, suggests that a relatively gross alteration of the molecule is necessary in order to destroy the activity. Trypsin is less resistant than the other ferments examined but it still requires from twenty-five to fifty times the dose necessary in the case of the Rous agent and at least ten times the dose for anthrax spores. In these experiments the trypsin was diluted and at pH 7.5. Strong trypsin in the acid state showed no evidence of any destruction with ten times the maximal period of irradiation. Although these results do not afford evidence as to the living nature of the Rous sarcoma agent, they do point to the fact that it differs widely in its make-up from the ferments so far examined. It appears, therefore, very improbable that this agent is a ferment in the accepted sense of the term.

Use of Elementary Body Suspensions from Vaccinia Filtrates in Smallpox Prevention—Eagles advances the possibility of elementary body suspensions as an alternative to other vaccine materials. These suspensions prepared from dermal lapine, represent the virus in its purest form, and they survive for long periods without serious deterioration in infectivity when stored in a cold room. Plain broth or physiologic solution of sodium chloride with the addition of a small amount of plain agar as a suspending medium exert a beneficial effect in conserving their potency. The suspensions possess the advantage over filtrates, which themselves keep extraordinarily well of consisting of practically pure virus particles, the serum proteins from the pulp having been to a large extent eliminated. The reactions produced by these suspensions of elementary bodies do not vary from those obtained with ordinary lymph as judged by animal tests. They are neutralized by vaccinia-immune serums and call forth an immunity response in rabbits shown by agglutinin production and by the fact that inoculated animals are later immune to an injection of lymph. This occurs

whether the intradermal or scarification method of inoculation is used. At present practically all human vaccinations for smallpox are made into the scarified skin. There is some hesitation to adopt the intradermal method. Yano (1934) used vaccine purified by adsorption and elution, having a strength of 1,000 minimal eruptive doses as determined by intracutaneous injection in rabbits. Altogether 613 persons were vaccinated subcutaneously, 0.3 cc being used as a dose for infants and 0.5 cc for adults. The series comprised primary and secondary vaccinations, as well as vaccinations on adults who had been vaccinated at least twice previously. Revaccination by the percutaneous route always gave negative reactions, and, although the time period following the subcutaneous vaccinations was not sufficiently long to warrant a conclusive opinion on the duration of immunity, there was nothing to suggest that it would prove less durable than that elicited by ordinary percutaneous vaccination. No mention was made of the incidence of complications contraindicating the use of the subcutaneous route. Suspensions of elementary bodies should lend themselves to vaccination whatever technique is employed, but would appear by virtue of their sterility and purity, to be particularly suitable for intradermal or subcutaneous inoculations. The ultimate test however, must be their behavior in routine human vaccination.

Fistula in Ano and Perianal Intramuscular Glands—Gordon-Watson and Dodd say that deep intramuscular perianal glands probably are vestigial and often lose connection with the anal canal by obliteration of the ducts during development. In some instances when the duct is patent infection from the anal canal takes place, in other instances infection may occur in the glandular substance when there is no direct communication with the anal canal or when the orifices of the ducts have become blocked by congestion of the mucosa and submucosa. On occasions when one of these glands has penetrated to the deep surface of the levator ani it may explain the development of a perirectal abscess and fistula. The presence of these deep glands emphasizes the importance of a careful search for a rectal opening when a supposed blind external fistula is being dealt with. A chronic origin of anal fistula may well be the truth in some cases should a mild infection of a perianal gland occur and the existence of a patent duct permit drainage into the anal canal. In the absence of a patent duct the infection of the perianal glands may be responsible for many of the abscesses which arise for no apparent reason. The existence of these perianal glands often with patent ducts leading into the rectum the tuberculous origin of many fistulas and the fact that malignant changes sometimes occur in fistulous tracts combine to emphasize the importance of histologic examination when operating for fistula in ano. Obviously it can happen only

occasionally, and then in the case of a recently formed abscess or fistula, that the epithelium of these glands and their ducts lining either abscess or fistula is recognized histologically. Once such a case has become chronic, granulation tissue will have replaced the epithelium, and the real origin becomes obscured.

Pathogenesis of Paget's Disease of the Nipple—Muir discusses intraduct carcinoma and its intra-epithelial mode of spread in Paget's disease. Intraduct carcinoma is a common chronic disorder which precedes the cancer age by a considerable period. It often breaks through the normal confines of the ducts and gives rise to ordinary carcinoma, but may exist for a long period without doing so; occasionally it leads to the relatively uncommon condition of Paget's disease. In the modes of spread of intraduct carcinoma the malignant change may arise in multiple foci, when the epithelial cells have assumed the neoplastic character, they may grow in masses within the ducts and come to form a sort of injection of them or a spread of cells with malignant properties in relatively healthy epithelium—the intra-epithelial spread of carcinoma. By intra-epithelial growth is meant the invasion of normal epithelium by cancer cells; the latter grow within the epithelium and destroy it to a varying extent the epithelium playing a passive part. The cancer cells may occur in masses in the invaded epithelium or they may be disseminated and occur singly, the latter condition being apparently due to their wandering in the epithelium. 1 Carcinoma may start in an epithelium and grow within it. The cells of the growth present different morphologic features and there may be aberrations in type. The growth often goes on for years, occasionally infiltration of the cutis vera follows, an epithelioma, a basal cell carcinoma or a growth of other type resulting. 2 A malignant growth infiltrating the cutis may invade the epidermis and spread within it. Carcinoma of the breast may occasionally invade the epidermis in this way, and the invading cells then behave in a fashion analogous to what is seen in Paget's disease. 3 The epidermis of the nipple may be invaded by cells of an intraduct carcinoma in the upper part of a duct of the nipple—the route of spread in this case is intra-epithelial throughout. This the author believes to be the ordinary mode of origin of Paget's disease. The intra-epithelial mode of spread occurs in the epithelium of the ducts and acini as well as in the epidermis of the nipple—the Paget cells are cancer cells growing in non-neoplastic epithelium. Paget's disease occurs only when the intraduct carcinoma is present in the upper portions of the ducts in the nipple and is due to the spread of the cancer cells from the ducts to the epidermis by the intra-epithelial route. Intraduct carcinoma in this situation is relatively uncommon, and hence Paget's disease is somewhat rare. Much more frequent is the occurrence of intraduct carcinoma in the ducts within the breasts, and then the ordinary result is a direct breaking through of the cells with the production of an ordinary infiltrating carcinoma. Intraduct carcinoma may lead to one or both lesions and thus Paget's disease may precede or may follow ordinary mammary carcinoma, or again may develop without the occurrence of the latter.

Osteo-Arthritis in Dorsal Intervertebral Joints—Shore states that osteo-arthritis of the small synovial joints of the vertebral column is to be distinguished from osteo-arthritis of the spine. In the pathologic anatomy of osteo-arthritis there are three stages of development. In the first the disease is indicated only by a fringe of osteophytes around the normal contact area; in the second by a zone of porous bone which separates the original contact area from a peripheral fringe of osteophytes and in the third stage all traces of the original contact area are lost and the surface may be grooved, polished and greatly deformed. The distribution of osteo-arthritis in the dorsal intervertebral joints which has not previously been recorded is set out in graphic form, and certain zones of special incidence are observed. The lumbodorsal outcrop is interpreted as the result of weight bearing in the joints of the dorsiflexed lumbar column and the absorption of the lower thoracic vertebrae into the lumbar curve as lordosis is established. By dorsocervical outcrop is suggested that in the main this outcrop is the result of the use of the upper limbs by movements of dorsiflexion transferred from the limbs to the thoracic skeleton and by associated action of the erector spinae muscle. This outcrop presents two peaks of higher incidence. 1 At the joint between the fourth

and fifth thoracic vertebrae is found the upper thoracic peak. It is suggested that this peak is due to dorsiflexion, which is a normal feature of inspiration accentuated with the onset of lordosis and kyphosis. 2 The cervicodorsal junction is marked by a cervicodorsal peak. It is suggested that the explanation lies in the powerful urge to keep the head upright in spite of kyphotic changes in the thorax. Columns greatly deformed with kyphosis often show that the head and neck are borne upright in spite of great postural difficulties. The cervical outcrop is probably due to weight bearing in the joints of the already dorsiflexed cervical vertebrae. Osteoarthritis in the anterior atlanto-axoid joint was found in about one-third of the columns that exhibit osteo-arthritis elsewhere in the dorsal intervertebral joints.

Liver Function in Pregnancy—During an investigation of liver function by means of the bilirubin excretion test of von Bergmann in pregnancy and its complications, Sullivan and his associates observed that during the first half of normal pregnancy the liver function is unimpaired but during the second half of normal pregnancy evidence of disturbed function can be demonstrated in at least 30 per cent of cases. The cause of the impaired excretory power of the liver during the later stages of normal pregnancy is undetermined, but the fact of its existence renders the interpretation of hepatic efficiency tests in abnormal cases difficult. Toxic patients with signs of renal insufficiency tend to show less retention of injected bilirubin than those with normal kidney functions. Thus, to some extent at least, it is possible to differentiate the toxemias of pregnancy into nephritic and hepatic types. So far as the bilirubin excretion test is concerned there is not sufficient difference between the changes in toxic patients and the results obtained in normal women during the later months of pregnancy to be of practical significance. In certain instances however especially during the early stages of pregnancy or in cases of extreme toxemia, the test may supply information of clinical importance. That the impairment of liver function which occurs during pregnancy, both normal and abnormal is of a temporary nature is indicated by the tendency for the results of the bilirubin excretion test to return to normal following termination of the pregnancy.

Ligature of Fallopian Tube in Incipient Salpingo-peritonitis—Elgart states that ligature of the open abdominal end of the fallopian tube in salpingitis prevents the escape of pus

into the abdominal cavity. If the acute abdominal condition is combined with a vaginal discharge, he performs a laparotomy with an 8 to 10 cm medial or paramedial incision in the hypogastrium. After the appendix has been removed the fallopian tube is massaged gently and, if pus is expressed, he then ligates and removes its abdominal end near the fimbriae and disinfects the remaining part of the tube with iodine. The end of the tube should be severed about 0.5 cm. from the ligature to prevent the latter from becoming loose. Ligature of the remaining tube should be performed only when a discharge of pus is present. In two patients who had a profuse discharge of pus, he also invaginated the ligated ends of the tubes but believes that this is unnecessary. The pelvis should be thoroughly cleansed before the abdomen is closed. Only a thin subcutaneous drain is necessary. The author points out that his method does not replace the resection of a chronic closed pyosalpinx (sactosalpinx) and is indicated only in a patient whose tube is for the first time acutely inflamed and at the beginning of her illness. Later, if desirable, the ligated and invaginated abdominal end of the tube can be rectified by a salpingostomy. He believes that the operation is practically safe, since of the fifty cases of incipient salpingoperitonitis that he has operated on not one has proved fatal. Fever, vomiting and pains disappear as a rule on the second or third day after the operation. In only one case did peritonitis spread into the abdomen, and that was when the fimbriae were cut too close to the ligature so that it later became loose. The subsequent development of a closed pyosalpinx (sactosalpinx) rarely follows ligature of the abdominal end of the tube because the pressure of the pus in the tube keeps patent the canal leading to the cavity of the uterus. Impermeability of the lumen of the tube between its ligated end and the cavity of the uterus is distinctly lessened. The ligature of the tube also protects the patient against subsequent extra-uterine pregnancy.

Resistance to Inspiration—Killick states that there is a limit to the power of suction that can be exerted during inspiration by any individual. Within the limit thus set by the capacity of the individual, the pressure head available to draw air through the resistance (i. e., the suction) can be varied according to the resistance and the rate of air flow necessary to provide adequate lung ventilation. When this limit is exceeded either by an increase in the resistance or by the increase in the ventilation necessary during muscular exertion adequate pulmonary ventilation becomes impossible and symptoms of distress are experienced. The effect of an inspiratory resistance on the type of breathing is variable, the most frequent response being slowing and deepening of the respiration. In certain subjects, however, this increased depth of respiration is not observed. Whatever the initial response, there is a general tendency as the resistance interposed or the work done by the subject is increased for the breathing to become less deep and more frequent. Analysis of samples of expired and of alveolar air showed that the most constant alteration in the respiratory exchange while breathing through an inspiratory resistance was failure of adequate carbon dioxide elimination. The important factors in bringing about the respiratory failure

which eventually results from breathing through an excessive resistance, are fatigue of the respiratory muscles and retention of carbon dioxide.

Inflammation Related to Surgery—Menkin discusses the relationship of inflammation to immunity and states that powerful necrotizing irritants produce as a result of an increase in capillary permeability and of lymphatic damage, an extremely prompt reaction, perhaps best termed fixation. By this process consisting in the rapid formation of a network of fibrin and of thrombi in lymph channels the area of injury is mechanically circumscribed and the dissemination of the irritant is prevented. *Staphylococcus aureus* is an example of such a bacterial irritant. Aleuronat is a chemical irritant of similar potency. Mild irritants on the other hand produce only a delayed reaction thus allowing relatively free penetration of the irritant into the circulation for a considerable interval of time. Occlusion of the draining lymph passages in such instances often takes place as late as two days subsequent to the inoculation of the irritant. Hemolytic streptococci exemplify this type of irritant. Another instance has been recently demonstrated by McMaster and Hudack, who showed that from twenty-four to forty-eight hours following a mere skin incision or a mild burn lymph drainage is increased. Subsequently the rate of flow is diminished. In relatively large suppurating or acutely inflamed areas the reaction of fixation may occur as early as thirty minutes after the injection of an irritant. This prompt response allows a definite interval of time for the relatively sluggish leukocytes to assemble for phagocytosis at the site of inflammation. The polymorphonuclear cells appear first and are displaced subsequently by the macrophages. This cytologic sequence is apparently conditioned by changes in the local hydrogen ion concentration. The reaction of fixation by circumscribing the irritant in the earliest phase of the acute inflammatory reaction plays a definite part in immunity, for it protects the organism at the expense of local injury. The disastrous effects resulting from untimely surgical intervention with such an effective inflammatory barrier are encountered, for example, in the *staphylococcus* or the anthrax carbuncle.

Leishmania Donovanii in Presence of Bacteria—Zia and Teng show that *Leishmania-Donovani* is able to survive, grow and flagellate in the presence of viable *Staphylococcus*

aureus, *Streptococcus haemolyticus* and *pneumococcus* type I and an undetermined type of *pneumococcus*. The Leishman-Donovan bodies may flagellate in the medium used after being associated with these bacteria for forty one hours. The resulting flagellates were able to live together with these bacteria for from ten to twenty-four days in the original tube and without subculture. The contaminating bacteria were recovered from the respective tubes at the time when the flagellate growth was most abundant. These various types of bacteria represent the kinds of bacteria with which leishmania may come into contact when discharged from the body of the host. *Staphylococcus* is ubiquitous and has been accused of being the most inimical to the leishmania. If Leishman-Donovan bodies can survive, grow and change to the flagellate form when associated with rich cultures of these bacteria, it seems likely that they may easily withstand contamination with other organisms. The results show that contamination with *Staphylococcus aureus*, *Streptococcus haemolyticus* and the *pneumococci* did not have any significant influence on the time required for the Leishman-Donovan bodies to flagellate. Neither had it any effect on the relative number of the flagellates. The authors' experiments in which *Leishmania Donovan* resists *in vitro* the presence of common gram positive organisms lend additional support to the hypothesis that the infectious agent of kala azar may be transmitted at least in some cases, through the agency of the secretions from the upper respiratory and upper alimentary tracts. When the contaminating organism was *Bacillus coli*, no flagellation was detected in either of the tubes. Forty-one hours after inoculation, when the other tubes were showing Leishman-Donovan bodies with beginning flagellation, and in some of these there were already a few actively motile flagellates there were only degenerating Leishman-Donovan bodies in the tubes contaminated with *B. coli*. The chromatin material in the parasites was pyknotic and the cells were shrunken. Six hours later no Leishman-Donovan bodies could be found, nor were there any flagellates. The authors suggest that under ordinary circumstances the Leishman-Donovan bodies discharged from the body through the lower alimentary tract are quickly destroyed by the ever present *B. coli*. But if the duration of the association of these two in the lower intestinal tract is shortened by increased peristaltic movements as in dysentery or diarrhea or if the parasites are protected by flakes of mucus, it would seem reasonable to think that the Leishman-Donovan bodies may survive and may serve as a source of infection.

Value of Certain Drugs in Treatment of Kala-Azar.—After treating sixty-three cases of kala-azar with a urea derivative of para-amino phenyl stibinic acid (urea stibamine), ninety-five cases with para-amino-phenyl-stibinic acid diethylamine (neostibosan) and eighteen cases with more than one drug at different times Lee and Chu conclude that 1. An adequate course of treatment with para-amino-phenyl-stibinic acid should consist of a dose from 1 to 15 Gm for children and from 15 to 25 Gm for adults. With para-amino-phenyl-stibinic acid diethylamine the dosage should be from 15 to 25 Gm for children and from 4 to 5 Gm for adults. 2. Para-amino-phenyl stibinic acid is not a pure chemical compound and has a varying antimony content, while para-amino phenyl stibinic acid diethylamine is a well standardized single chemical compound. In their therapeutic value in kala azar para-amino-phenyl-stibinic acid is definitely more potent but at the same time more toxic than para-amino-phenyl-stibinic acid diethylamine. 3. Patients treated with either of these drugs must be observed for at least seven months a year if possible before cure can be pronounced. This is more important with patients treated with para-amino-phenyl-stibinic acid diethylamine than with those treated with para-amino-phenyl stibinic acid. The recovery of parasites from a spleen or liver puncture one month after the completion of a course necessitates prompt institution of further treatment. 4. Future improvement in the chemotherapy of kala-azar lies in the production of an organic pentavalent antimony compound as well standardized and non-toxic as para-amino-phenyl-stibinic acid diethylamine, but possessing the high therapeutic potency of para-amino phenyl-stibinic acid.

Pancreatic Changes in Diabetes.—Labbé and Petersco found that the histologic changes in the pancreas in diabetes mellitus were diverse. Outside of bronze diabetes, in which the insular and acinous changes are marked and the hemosiderin formation is added to the diabetic lesions, they found it impossible to establish a relation between the clinical type of diabetes and the character or intensity of the changes. It seemed only that the islet sclerosis were more often encountered around middle age, while the hydropic and pycnic degenerations of the islet epithelial nuclei were found especially in young diabetic patients. There are cases of diabetes without pancreatic lesions or with lesions so minimal that one cannot attribute the disorder of the sugar metabolism to them. These cases showed no clinical peculiarity during life which might distinguish them from others. The explanation is uncertain and there is insufficient evidence for either assuming a cerebral center, disorders of other endocrine glands, or an inactivation of a normal pancreatic secretion. The authors are more inclined to believe that the histologic lesions are not always a reliable index of the functional state of the organ and that histology is a less important index than physiology in assessing the functional value of the pancreatic apparatus. It is possible that histologic technic will be perfected to such an extent that the exact physiologic value of the cells can be determined, but this desideratum has not yet been reached.

*Therapeutic Action of Lumbar Puncture in Sydenham's Chorea R A Khersonsky—p 275

Lumbar Puncture in Chorea.—Khersonsky made lumbar punctures on twenty-five patients with Sydenham's chorea. In two cases the puncture was repeated two and three times. They were made with the patients recumbent and with a needle of a caliber not larger than that usually employed with a syringe of 10 cc capacity. From 8 to 10 cc of spinal fluid was withdrawn. Effectiveness was judged by the decrease in intensity and frequency of the involuntary movements and by the degree of disappearance of the so called minor signs. The patients received both before and after the punctures the usual medical treatment, consisting of sodium salicylate and solution of potassium arsenite by mouth. Improvement was recorded only if it occurred within the first five days following the withdrawal of spinal fluid. Twelve of the twenty-five patients were markedly improved, while thirteen were unaffected. Of the ten serious cases improvement resulted in six, and of the fifteen mild cases six were improved. Thus the more serious cases showed a higher percentage of improvement. The therapeutic effect may be due to reflex increase of the permeability of the blood-brain barrier thus allowing an easier penetration of antibodies and salicylates into the nervous system. From the symptomatic angle, the favorable effect of lumbar puncture does not affect relapses or protect against cardiac complications.

*Amphoric Breathing in Therapeutic Pneumothorax Warembourg and Roose—p 843

Amphoric Breathing in Pneumothorax.—Warembourg and Roose investigated the variability of acoustic signs in therapeutic pneumothorax and directed their work toward the elucidation of amphoric breathing and the effect on this sign of

bronchopleural communication, intrapleural pressure, the quality of the retracted lung stump and the state of the pleural coat. From the clinical study of thirty-eight patients they concluded that bronchopleural communication is not necessary for the appearance of amphoric breathing and that it has little influence on this sign. There exists, however, an optimal pleural pressure for the appearance of amphoric breathing. In the transmission of vibrations from the glottis by way of the lung stump, the noncollapsed tuberculous areas of this stump seem to play a dominant part, especially if endowed with expansible properties. A tortuous pleural cavity tends to suppress the amphoric breathing. Finally the individual differences of each case may give rise to all possible combinations of factors. It is thus advisable to consider them statistically rather than individually in order to obtain significant results.

Parathyroids and Carbohydrate Metabolism—Ferrannini studied the action of parathyroid extract on the glycemic curve and on the glycosuria of patients presenting different stages of diabetes. In normal subjects the parathyroid extract lowers the glycemic rate during fasting and increases carbohydrate tolerance. The action of the parathyroid extract on the glycemic curve, when compared with that of epinephrine is almost like that of insulin. In diabetes the parathyroid extract lowers the glycemic curve and the glycosuria on fasting. Following intramuscular administration of 1 cc. of parathyroid extract, the author obtained in ten cases examined a clear hypoglycemic effect, slightly lower than that determined by insulin. In five diabetic patients the author studied the glycemic curve and the rate of glycosuria after injecting parathyroid extract and insulin one hour apart. He observed that the parathyroid extract when administered with insulin may increase the hypoglycemic action of the insulin, may scarcely modify it, or may slightly inhibit it. There is no doubt about the insulin-like action of parathyroid extract in normal subjects and in diabetic patients. The parathyroid extracts act by way of the parasympathetic system, since the parathyroids with the pancreas and other endocrine glands form part of the endocrine sympathetic group of glands that preside over anabolic processes. The author suggests the existence of a functional synergism between the parathyroids and the pancreas in relation to carbohydrate metabolism.

Internal Milieu in Diphtheria.—González and his collaborators studied the prognostic value of the biochemical changes of the blood in diphtheria. They made determinations of the urea, dextrose, cholesterol, phosphorus, chlorides, calcium and creatinine in the blood, as well as of the pH of the blood. For the estimation of the results the authors place the patients into three groups, according to the type of diphtheria they suffer: common, submalignant and malignant diphtheria. The authors conclude that urea in the blood increases in complicated forms of the three groups. The prognosis depends on the quantity of urea in the blood as related to the clinical form of diphtheria. In the same type of diphtheria the higher the

uremia the graver the disease, but the prognosis is better in patients suffering from the common and submalignant types of diphtheria and giving 1 Gm of urea per thousand grams of blood than in those suffering from the malignant form and giving less than that quantity. Urea in the blood amounts to 4 Gm per thousand grams of blood, or even more, only in malignant diphtheria, in which the prognosis is based on the type of the disease rather than on the quantity of urea in the blood, which may become even normal in cases in which the disease follows a fatal evolution. The alterations in the glycemia and cholesteremia are neither constant nor intense, their changes are not parallel and have no prognostic value. They indicate the presence of metabolic organic or functional disturbances of which they are not the etiologic agents and which do not improve by the administration of dextrose, insulin and cholesterol. The slight variations of calcium, of phosphorus and the pH of the blood in diphtheria have no prognostic value and the creatinine does not change. Hypochloremia that exists in the acute period bears no relation to uremia. Hyperuremia has no peculiar characteristics, and its prognostic value is the same as in any other infectious disease.

The Basal Ganglions and Epilepsy—Hanón believes that epileptic fits are due to ischemia of the cortex and of the basal ganglions of the brain originating in a transient cortical and ganglionic arterial vasoconstriction of sympathetic origin. Ischemia modifies the humoral environment of the cells that react with the production of nervous stimuli and with a reflex hyperexcitability on the distant and neighboring cerebral centers. The simultaneous production of nervous stimuli from the frontal, parietal, rolandic, temporal and striated nuclei (in different proportions) determines the onset of the tonic phase of the epileptic fit. When the arterial spasm subsides or disappears, the stimuli from the rolandic area are predominant and determine the production of the clonic contractions. The author bases his theory on the therapeutic results of sedatives (phenobarbital, bromides and borates) given in epilepsy and on the presence of anatomic lesions in the basal ganglions found at necropsy of five epileptic patients. In these cases the ganglions proved the previous existence of recurrent vascular and nutritional alterations.

- Gonadal Hormones Their Characteristics Chemical Composition and Artificial Production A Butenandt —p 781
- *Postoperative Cerebral Edema H Hoff and L Schönbauer —p 786
- Water Economy and Acid Base Equilibrium F Hoff —p 789
- *New Method for Treatment of Diphtheria Bacilli Carriers G Paschlaw —p 791

Postoperative Cerebral Edema—Hoff and Schönbauer say that cerebral edema is one of the most serious problems that develop following operations for tumors of the brain, and one of the chief causes of cerebral edema is preliminary roentgen irradiation. The authors are convinced that, when the cranium is closed, roentgen irradiation of cerebral tumors is inadvisable. Moreover, if, as is usually the case, surgical treatment becomes necessary, the conditions for the operation become more unfavorable, because valuable time has been lost and the danger of edema is greater. Roentgen therapy was likewise of little avail in cases in which a glioma was found that could not be completely removed. The authors observed favorable results in only four out of a total of 120 cases of glioma. In some cases they gained the impression that the tumor grew more rapidly under the influence of roentgen therapy. The four cases that responded to roentgen irradiations were blastomas of the medulla, and the authors think that the success of the postoperative roentgen irradiation depends on the type of tissue of which the tumor consists. Irradiation with radium likewise proved of little avail in the postoperative treatment of gliomas. The authors reasoned that, if cerebral edema is a form of exudative inflammation, it should yield to the measures suggested for exudative inflammation. Starting from the idea that amidopyrine reduces the permeability of the vessels, Eppinger suggested large doses of that substance for the treatment of exudative inflammations. The authors applied this suggestion to the treatment of cerebral edema, irrespective of whether it was a postoperative condition or was induced by roentgen rays.

They administered daily from 3 to 5 Gm, either by mouth or by rectum, and found this measure highly effective. Encouraged by the results, they resorted to the administration of large doses of amidopyrine also in cases of encephalitis and obtained good results during the acute stage. In hemorrhagic arachnoiditis amidopyrine proved highly effective, but it was not in the sequels of encephalitis and in poliomyelitis.

Treatment of Diphtheria Bacillus Carriers—Paschla treated children, carriers of diphtheria bacilli, with a tincture having the following constituents: 11 per cent formaldehyde, 20 per cent rhodan alkali, 2 per cent gelatin, 15 per cent brandy, 1 per cent oil of peppermint, and distilled water to make 100. To counteract the diphtheria bacilli harbored in the pharynx, the children gargled twice each day with a 1:50 or a 1:75 solution of the tincture (20 drops for half a glass of water). However, for the disinfection of the nose, a higher concentration had to be used, a 1:20 or even a 1:10 solution. Drop instillation proved ineffective for nasal administration, but treatment by means of tampons, saturated with a 1:10 solution and introduced twice daily, was highly effective. The author employed the tampon treatment in thirty-four diphtheria bacillus carriers, ten of whom had nasal diphtheria. The time required for clinical cure varied between three and sixteen days, the average being six days.

A Follow-Up Study of Gastric Operations—Jaeger reports a follow-up study of 400 patients in whom one or more surgical interventions for the cure of ulcer disease failed to bring about relief from symptoms. In 166 of these a "corrective operation" had to be performed. The operative procedure calling most frequently for a secondary corrective operation was gastro-enterostomy. The most frequently instituted corrective procedure was the Billroth II operation. The acid values of the stomach contents were effectively lowered by gastric resection, whereas the emptying time was approximately the same after all types of operative procedure. It was most satisfactory, however, after the Billroth I operation. The author is opposed to gastro-enterostomy because of the frequency of occurrence of the marginal peptic ulcer as well as because of its inability to influence the mechanism of acid production. This operation should be reserved for cases of pyloric stenosis or when special indications exist. The Billroth I or the Billroth II operation of partial gastric resection is advised as the procedure of choice whenever possible.

Complications Arising from Intravenous Drip—According to Müller the continued intravenous drip has been in use in Fritz König's (Würzburg) clinic for the past three years. The method was adopted in desperate cases as the last resort. The results were encouraging, as 33 per cent of cases of that type were saved. The author however is aware of certain dangers inherent in the method itself. The complications caused by the method are thrombosis at the site of transfusion and pulmonary embolism. Considerations of the dangers to be avoided in the employment of the method led the author to the following conclusions: 1. The continued intravenous drip is contraindicated in the presence of cardiac and pulmonary disturbances as well as in the presence of nephritis or after a nephrectomy. 2. Because of the danger of thrombosis and infection, the duration of transfusion must be limited and the transfusion renewed only in exceptional cases. The procedure should not be used for the immediate postoperative shock that can be handled by simpler means but should be reserved for the critical condition arising on the fourth, fifth or sixth day as the result of loss of vascular tonus occasioned by the post-

operative breaking down of albuminous bodies. Addition of foreign albumins, such as the various serums, is contraindicated because of the possibility of protein shock. Painstaking asepsis at the site of transfusion diminishes the danger of thrombosis.

Blood Protein in Multiple Myeloma and Takata's Reaction—Gros gives the histories in two cases of multiple myeloma. The behavior of one of these cases differed from that of the cases recorded in the literature. A hyperproteinemia was present, which was not, as in the other cases, caused by euglobulin but by pseudoglobulin I and II, respectively. The assumption that the hyperproteinemia in multiple myeloma is entirely due to an increase in euglobulin does not seem to tally with these facts. In this connection the author discusses the dependence of the different protein fractions on the stage of development of the myeloma. On the basis of this case and of the other cases that have become known thus far, he shows that different groups of symptoms have a relationship to the disturbance of the protein metabolism in myeloma. These differences are not caused by the abnormal anatomic nature of the cells. In accordance with this, the author advances the theory that a formerly unknown functional disturbance of a certain group of cells of the bone marrow is responsible for this change in the protein metabolism. In the course of further studies he obtained a positive Takata reaction in the blood of the myeloma patients. In spite of careful functional tests of the liver, he was unable to detect hepatic disturbances and he deduces from this observation that myeloma with its hyperproteinemia is another disorder, in which the Takata reaction cannot be considered a specific test for cirrhosis of the liver. He discusses the significance of the serum protein bodies for the development of the Takata reaction and on the basis of analyses of the serum protein bodies in cirrhosis of the liver and in myeloma, he suggests that, if the Takata reaction is solely dependent on deviations of the serum protein bodies, the alterations in the albumin globulin ratio with increase in the pseudoglobulin (the increase in pseudoglobulin I probably being sufficient) are probably decisive for the outcome of the reaction. A positive reaction is obtained also when euglobulin and pseudoglobulin I are increased. In the latter case the flocculation zone shifts to the side of the higher concentration.

*Studies on Occurrence and Behavior of Sudanophil Leukocytes in Normal Nurslings and in Sick Children L. Moschkowitz—p. 278

Severe Intracranial Hemorrhages That Develop During Spontaneous Deliveries and During Cesarean Operations A. Ehergenyi—p. 291

Occurrence of Sudanophil Leukocytes in Children—Moschkowitz studied the occurrence of sudanophil leukocytes in sixty-one normal and sick children. He found that sudanophil leukocytes may appear under normal conditions, their upper physiologic limits being at 15 per cent. In normal nurslings he observed an alimentary sudanophilia (following ingestion of a butter and flour gruel and of sweetened condensed milk), which reached its maximum (from 15 to 23 per cent) after two hours. This value is equivalent to the maximum of chylomicrons in breast-fed nurslings. The author further studied the behavior of sudanophils in children with pneumonia and empyema and in a number of other disorders. In eleven cases of pneumonia he always detected an increase in the sudanophils, the percentages being between 20 and 35. In parapneumonic empyemas the increase was even more pronounced (between 20 and 40 per cent), following successful operative treatment of the empyema however the numbers decreased to normal. The increase in sudanophils was especially pronounced in appen-

dicitis and in perityphlitic abscess (from 20 to 52 per cent) Here too the number decreased after appendectomy or drainage of the perityphlitic abscess The examination of eight children with eczema and exudative diathesis disclosed a moderate increase in sudanophils In these children the sudanophilia is probably the result of a disturbance of the fat embolism Observations made in certain disorders of the central nervous system were especially noteworthy When, as it happened here, in a case of postdiphtheric encephalitis and in a case of obstetric cerebral hemorrhage, there is a resorption of anatomically impaired cerebral substance, the leukocytes of the blood stream may become laden with products of fatty decomposition similar to the fat granule cells that are found in the foci themselves The sudanophils were increased (22 per cent) in meningococcal meningitis and there was no increase in tuberculous meningitis A greatly emaciated child with pylorospasm had an increased number of sudanophils (20 per cent) It is probable that in this case the extensive decomposition of tissues increased the fat content of the blood and that the fat was phagocytosed by the leukocytes In a severe case of diabetic coma (blood sugar 1,400 mg per hundred cubic centimeters) 38 per cent of sudanophils were detected Here the sudanophilia was the result of a pure fat phagocytosis, for the blood of these patients contains a great amount of fat (lipemia)

Aspects of So Called Blood Group Ferment F Schiff and F A Burón—p 710

*Hemorrhagic Hereditary Telangiectasia (Osler's Disease) R Kosiner—p 713

Follicle Maturation Hormone in Urine of Young Men—Goldhammer and Loewy examined the urine of sixty-four men between the ages of 19 and 51 by means of the Aschheim-Zondek test for the presence of the follicle maturation hormone Thirty-two of them had a defective sympathetic nervous system and ejaculatio praecox, and all except two of these were of the leptosomic type. Twenty-one of these, or 65.6 per cent gave a positive Aschheim-Zondek reaction However, of the thirty-two men who did not have a defective sympathetic nervous system and were not leptosomic, twenty-six gave a negative reaction The authors conclude from this that in men who have a defective sympathetic constitution and in whom ejaculatio praecox is a constant sign there exists a primary hyposecretion of the gonads In this connection it is pointed out that Anselmino and Hoffmann detected the synergistic gonadotropic factor in the urine of castrates and of women in the menopause The authors consider it not impossible that in their own studies it was the same factor However, their conclusions regarding the sexual constitution and the general constitution of their cases remain the same, regardless of whether later studies prove that not the follicle stimulation factor of the anterior pituitary-like principle but rather the synergistic factor is increased in the urine

Sedimentation Speed of Erythrocytes and the White Blood Picture—Behr points out that the theory has been advanced that accelerated sedimentation is the result of an alteration of the plasma protein in favor of the globulin-fibrin fraction Numerous tests have proved however, that this theory is erroneous and it has been observed that animal bloods with extremely high fibrin content have an extraordinarily low sedimentation speed Since on the basis of his own studies the author was of the opinion that there is a connection between the sedimentation speed of the erythrocytes and the reacting mesenchyma, he compared the sedimentation speed and the white blood picture of sixty-nine patients At the same time he determined the protein fractions, the rest nitrogen the bilirubin content of the serum and the ratio of erythrocytes to plasma He found that the sedimentation speed of the erythrocytes is not noticeably modified by the plasma protein The sedimentation

speed is accelerated by the reaction of the active mesenchyma, which answers a pathologic irritation by elimination of leukocytes with basophil granules The basophil granules seem closely related to the globulins, and, as regards their morphology, they belong to the thrombocytes

A Case of Osler's Disease—Kosiner describes the history of a woman, aged 53, who asked medical advice on account of diabetes mellitus and heart disease. The family history revealed that she descended from a family with a hemorrhagic tendency At the age of 28 she had had severe epistaxis, and years later "red dots" appeared on the face, which gradually became more numerous and finally involved also the tongue The patient frequently experienced a burning sensation in the tongue, and later red dots appeared on the terminal phalanges of the fingers and there was bleeding from the nail beds In recent years the nasal hemorrhages became more frequent and occasionally there was bleeding from the tongue. The cheeks of the patient showed, almost symmetrically arranged, dotlike telangiectasias branching out into fine vessels Such vascular dilatation and small angiomas were noticeable on the ear and on the lower lip Telangiectasias were found on the lower angle of the nasal septum The tongue showed dark red wartlike elevations on the tip and on the sides and an angioma underneath. Symmetrically arranged angiomas were found in other parts of the body The terminal phalanx of both thumbs was unusually wide and short (brachyphalangia) The family history disclosed that this deformity had occurred in the ascendancy of the patient. On the basis of the histologic aspects, the author concludes that a hereditary degenerative disturbance in the structure of the mesenchyma exists in hemorrhagic hereditary telangiectasia. He points out that the disorder concurs with other hereditary anomalies, such as brachyphalangia and diabetes mellitus

*Inhibition of Diuretic Action of Coffee by Milk and Milk Products. K Hitzberger and D Roller.—p 133

Improvement of Therapeutic Action of Blood Transfusion—In trying to increase the stimulating action of blood transfusion, Boller and Fenz thought that the behavior of the leukocytes following a blood transfusion would provide a point of attack. Other investigators had observed that the leukocytes decrease immediately after a blood transfusion and do not start to increase again until from three to five hours later In view of the fact that in some cases the donor had higher leukocyte values than the patient, this phenomenon seemed surprising and it was assumed that the leukocytes are stored in the blood depots of the patient and enter the blood stream gradually Since the leukocytes supposedly have an especial significance for the development of bactericidal substances, it seemed possible to increase the action of the transfusion by driving the leukocytes into the blood stream and thus to increase the stimulation of the reticulo-endothelial system The authors injected five hours after a blood transfusion, that is, at the time when presumably the lowest leukocyte values existed, 0.75 mg of epinephrine In the first patient in whom this was done there developed severe chills and high fever In the course of the chills the leukocytes increased to approximately three times the initial number The temperature decreased and two days later the patient was free from fever In a second case the results of the epinephrine injections were even more favorable and the authors decided to employ it in other cases They report the clinical histories of five cases of acute sepsis, in which the combination of blood transfusion and epinephrine injection produced favorable results The combination proved ineffective in cases of chronic sepsis In order to gain a better understanding of the changes that take place in the blood following blood transfusion and epinephrine injection, the authors employed the combination in several cases of blood disease, and they found the same changes that are observable in patients with sepsis

Inhibition of Diuretic Action of Coffee by Milk—Hitzenger and Roller call attention to the widely accepted belief that the addition of milk or cream to coffee inhibits the "harmful" effect. The authors decided to study the diuretic action of coffee in this respect. Persons who submitted to tests received on the first morning 400 cc of water with 30 Gm of sugar and 40 Gm of bread, on the second day they were given 400 cc of black coffee with 30 Gm. of sugar and 40 Gm of bread and on the third morning they received the same as on the preceding day, except that 60 cc of milk was mixed with the coffee. The authors found that on the first day the urine elimination was 205 cc. in four hours, on the second day 510 cc and on the third day 312 cc. This indicates that the addition of milk inhibits the diuretic action of coffee. Nothing definite is as yet known about the causes of this phenomenon, but it has been assumed that the tannic acids of the coffee combine with the proteins of the milk to form compounds the resorption of which is rather difficult, and thus the resorption of the caffeine is retarded. However, the authors question that the caffeine is the chief factor in the diuretic action of coffee and cite experiments proving that other substances in the coffee play a part. They investigated also what substance in the milk exerts the antidiuretic effect. On the basis of their tests they question Starkenstein's assumption that the protein bodies of the milk are chiefly responsible, for they found that the addition of cream to coffee has an even stronger antidiuretic effect. Consequently they believed that fatty substances were responsible, and they found this corroborated by the addition of melted butter, which resulted in the strongest antidiuretic effect. In trying to determine which of the fat like substances in milk and its products exerts the antidiuretic action the authors found that lecithin plays an important part but they are as yet unable to say whether there are still other lipoids involved.

Degenerative Diseases of Vertebral Column.—Kienböck thinks that the benign chronic diseases of the vertebral column are not sufficiently known as yet and he describes three of them. In his discussion of Scheuermann's disease he points out that this disorder is essentially a developmental and growth disturbance of the vertebral epiphyses and of the intervertebral disks. The disorder probably begins during childhood, but the symptoms in the form of fatigue and pains as a rule, develop only between the ages of 14 and 16 years and recur again in later life. Roentgenoscopy discloses Schmorl's cartilaginous nodules, that is, projections of the intervertebral cartilage due to defects in the terminal plates also cuneiform vertebrae flat vertebrae and vertebrae that are both wedged and flattened. The patients generally have a slight kyphosis which is frequently combined with scoliosis, but in some instances the normal curvature of the dorsal vertebral column is absent so that it appears like a straight stick. The author discusses deforming spondylarthrosis. His observations disclosed that it frequently develops on the basis of Scheuermann's kyphosis. The symptoms caused by this disorder curvatures and pains frequently do not develop until middle age or even later in life. The process often involves not only the dorsal but also the cervical and lumbar portions of the vertebral column. The changes progress with advancing years. Roentgenoscopy discloses in addition to the changes caused by the arthrosis also the sequels of Scheuermann's kyphosis. There is an anterior beveling of the marginal rims of the vertebrae also peculiar

exostoses, cuneiform vertebrae, flat vertebrae and vertebrae that are wedged and flattened. The pains caused by the deforming spondylarthrosis depend on the site of the principal changes. They may be localized in the neck, occiput, face, shoulders, arms, trunk, the sacral region and the legs (sciatica). These neuralgic pains are caused by the lateral projection of the proliferations and by a lowering of the vertebral bodies with contraction of the vertebral foramina and pressure on the nerve roots. The author stresses that it is erroneous to consider this disorder clinically unimportant, for it may lead to spastic paraparesis or, rarely, to hemiparesis. Moreover, the posteriorly projecting proliferations of the marginal rims may exert pressure on the spinal cord. Traumas may result in the splitting off of the exostoses and in the fracture or bone bridges. Softening of the exostoses may be followed by infectious osteitis or by tuberculosis. The third disorder to which the author gives his attention is porotic kyphosis. This disorder is usually a partial manifestation of a generalized osteoporosis and is accompanied by endocrine disorders, or by obesity or anemia. The porosis involves the entire vertebral column and is progressive. It may be combined with Scheuermann's disease and for this reason the same types of vertebral deformities may appear as in that disorder. However, in addition to these changes there are also biconcave vertebrae (fish vertebrae) and large Schmorl's cartilaginous nodules. Neuralgias are a frequent symptom of this disorder and may be brought about by a false step or by a sudden movement. Spastic paraplegia may develop as the result of the pressure exerted by the deformed vertebrae on the spinal cord.

Total Irradiation with Roentgen Rays in Polycythemia Rubra.—Sgalitzer decided to try roentgen irradiation of the entire body in the treatment of polycythemia rubra, a method that Teschendorf had introduced for the treatment of leukemia. He applies somewhat larger doses than are employed in leukemia. He uses an apparatus which, with 170 kilovolts, with a filter consisting of 0.5 mm of zinc and 1 mm of aluminum, with a tube tolerance of 3 milliamperes and with a focus distance of 30 cm produces the unit skin dose in approximately thirty minutes. He applies the total irradiation from a distance of from 150 to 200 cm, the rays being applied alternately to the dorsal and ventral aspects of the body. Each irradiation lasts about twenty minutes and applies about 25 roentgens to the body surface. The eyes and the genital region are excluded from the influence of the rays by protective covering. The irradiations are given on six successive days, after which there follows a pause of about a week. At the end of this week the blood is carefully examined especial attention being given to the leukocytes to guard against their too drastic reduction. The power of resistance of the leukocytes varies considerably, so that in some cases longer pauses become necessary than in other cases. As a rule, the irradiations should be given in such a manner that the number of leukocytes does not fall below 3000. To achieve this it is necessary to lengthen gradually the pauses between the series of irradiations. The erythrocytes occasionally show at first a temporary increase, but this is soon followed by a reduction that continues for several weeks or even for months. Among the patients in whom the author employed the total irradiation were some in whom the local roentgen therapy had not been entirely successful, while in other cases spleen therapy and other measures had been without success. The general reactions varied greatly, in some patients they were slight while in others they were severe. However the majority of the patients soon felt better in spite of the irradiations. The fatigue, the headaches the rushing of the blood to the head and the other symptoms soon disappeared. The hyperemia of the face was one of the last symptoms to disappear. The author's hope that the total irradiations might effect complete cure was not realized, for relapses occurred after from eighteen months to five years. The results were most lasting in the cases in which the irradiations were carefully distributed over several weeks and in which the blood status had been kept under strict control.

Myasthenia Gravis Pseudoparalytica and Tumor of Thymus.—Gold describes the history of a woman aged 31, who three years before had had a temporary paralysis of the eye muscles which recurred a year later. Otherwise the patient

had been well until eight days before hospitalization, when swallowing and speaking became difficult. The patient was now emaciated and hardly able to sit up in bed. With the exception of a paresis of the right levator palpebrae superior and of the right facial nerve, the cerebral nerves seemed to be free from pathologic changes. She died later with the symptoms of suffocation. The necropsy disclosed in the anterior mediastinum, directly behind the sternum, above the upper portions of the pericardium, a roundish, sharply defined nodule 4 cm. in diameter, and near it there were remnants of atrophic, milk-white thymus tissue. Histologic examination of the nodule disclosed a thymoma. Histologic examinations were made also on numerous muscles and they revealed the presence of foci of infiltration characteristic of myasthenia. The author discusses and evaluates the various theories about the pathogenesis of myasthenia gravis pseudoparalytica. He reaches the conclusion that neither the pathologico-anatomic nor the pathologicophysiology aspects indicate a causal connection between myasthenia gravis and the parathyroids. He was unable to corroborate Marburg's suggestion regarding the existence of a disturbance in the magnesium metabolism. The assumption that myasthenia develops on the basis of a status thymico-lymphaticus could likewise not be supported by the pathologico-anatomic aspects. The author thinks that by searching for and extirpating a tumor of the thymus it may be possible to exert a therapeutic influence on the course of myasthenia gravis and thus contribute also to the clarification of the pathogenesis of the disease.

Cockroaches as Carriers of Disease—Jettmar made bacteriologic studies on two types of cockroaches, *Phyllodromia germanica* and *Periplaneta orientalis*. He first studied the normal intestinal flora of these types of cockroaches and found that it nearly always contains staphylococci and also streptococci, the latter especially in the alpha forms of the viridans type. Later he studied the intestinal contents following artificial infection and found that the infected cockroaches are capable of transmitting pathogenic streptococci. He observed that the excrement of these animals contains viable and highly virulent streptococci for days and even weeks after the infection. In the conclusion he gives advice regarding the extermination of cockroaches.

*Action of the Urine of Pregnancy on Human Ovaries A. Westman —p. 1090

*Growth and Atresia of Follicle During Pregnancy K. Tietze and R. Wegener —p. 1097

Spontaneous Rupture of Cervix with Fatal Outcome G. Gergely —p. 1111

Action of the Urine of Pregnancy on Human Ovaries—Westman administered a preparation of anterior pituitary-like principle from the urine of pregnancy, the efficacy of which he had verified in tests on rats, before his three patients underwent gynecologic operations. He observed intensive hyperemia, dilated veins and, around the follicles, around the corpora lutea and in the stroma, he found hemorrhages. The endometrium always showed the status characteristic for the corpus luteum phase, except that the blood perfusion seemed to be somewhat more pronounced. He concludes that anterior pituitary-like principle produces in human ovaries the same changes that have been observed in animals, namely, maturation of the follicle, hemorrhage and formation of the corpus luteum, provided sufficiently large amounts are given. In the cases reported here, from 3,600 to 5,000 rat units was administered.

Growth of Follicle During Pregnancy—Tietze and Wegener describe histologic changes that develop in the ovaries in the course of pregnancy. Their observations were made on the ovaries of sixteen women who were operated on during pregnancy either on account of cervical carcinoma or because of peritonitis following attempted abortion. They found that the degeneration of the corpus luteum begins at various periods. It may begin during the second month or only during the last months. The factor that determines the onset of the degeneration does not involve the entire corpus luteum at once but rather develops in foci and progresses slowly. The authors gave their attention chiefly to the follicle apparatus. They observed growth

of the follicle during all periods of pregnancy. They intentionally avoid the term ripening, because they want to restrict that term to the follicles that are brought to ovulation outside the period of pregnancy. Follicles do not ripen during pregnancy and almost never grow beyond the 5 mm. size, for as a rule they become atretic before they have reached this size. The authors gained the impression that follicular growth decreases with the advancement of pregnancy. Nevertheless, there were some cases of advanced pregnancy in which the follicular growth was not lessened. Moreover, there is no connection between the number of follicles and the condition of the corpus luteum. They paid attention also to the luteinization of the theca and gained the impression that it depends on the advancement of the pregnancy, of the degeneration of the follicle and of the atresia of the follicle, that is, it progresses as they do. But, since these factors do not run parallel, manifold pictures may develop. If pregnancy and degeneration of the corpus luteum are advanced, luteinization of the theca may take place even if the follicles are still growing, but not so noticeably. The growing follicle of any size may become atretic and its theca may become luteinized. The authors reach the conclusion that the development of follicle material continues. They are unable to say whether the number of follicles is reduced during pregnancy, but they think it unconvincing that the corpus luteum of pregnancy inhibits formation and growth of follicles. They admit as certain the inhibition of the ripening, however, the development of the follicle up to the 5 mm. size is not inhibited.

*McClure Aldrich Intradermal Test in Detecting Occult Edemas Ya. S. Khentov and V. S. Kurbatov —p. 531

Intradermal Test to Detect Occult Edemas—Khentov and Kurbatov report the results of 249 McClure-Aldrich tests performed in 131 cases made up in groups (1) cardiovascular, (2) renal, (3) infections, (4) malignant neoplasms, (5) endocrine and metabolic and (6) miscellaneous. The test consisted of an intradermal injection of 0.2 cc. of 0.8 per cent physiologic solution of sodium chloride. The resulting wheal is absorbed under normal conditions in from fifty to ninety minutes. The cardiac and renal patients exhibited an acceleration of water resorption proportional to the degree of existing edema. In localizations with pronounced edema the intradermal wheal disappeared in from five to two minutes. Accelerated water resorption in the compensated cases indicates the existence of occult edemas. The test enables one to determine the state of fluids in the organism, whether bound or free. Acceleration of the resorption of the wheal will be noted with the leg lowered if the tissue fluids are in a free state. It will not be affected by lowering the limb if the water is bound. Certain infections affect the water exchange of the tissues, while others do not. Rapid resorption of the wheal in infectious diseases suggests the existence of occult edemas and an increased amount of retained tissue fluids. Malignant neoplasms with their toxemia lead to a preedematous state, e. g., to occult edemas.

THE DIAGNOSIS AND PROGNOSIS OF EPITHELIAL TUMORS OF THE LARGE BOWEL

CHAIRMAN'S ADDRESS

WALTER A. FANSLER, MD

Assistant Professor of Surgery University of Minnesota Medical School
MINNEAPOLIS

It would seem that the chairman's address should deal with a subject which is of interest to gastroenterologists and proctologists alike, and for this reason I have chosen to call or recall attention to the question of the diagnosis and prognosis of epithelial tumors of the large bowel. Tumors actually arising from the bowel epithelium must be differentiated masses projecting into the bowel lumen and are merely covered with bowel mucosa. In cases in which the bowel mucosa covering a mass is normal there is no question, but when the mucosa is ulcerated or when a tumor has broken through the mucosa and is projecting into the bowel lumen, as is sometimes the case with prostatic carcinoma or metastatic nodes in the rectovesical pouch, or culdesac of Douglas, some confusion may arise. Certain tumors arising in the bowel wall, such as lipomas or myxomas, may give this picture, as may masses arising entirely outside the bowel, as in the case of presacral dermoid cysts or meningocele. Likewise inflammatory conditions with ulceration, such as amebic dysentery, ulcerative colitis, tuberculosis, actinomycosis, syphilis, lymphogranuloma inguinale, diverticulitis or inflammatory conditions due to intestinal parasites, may simulate to some degree epithelial tumors. If the existence of these conditions is kept in mind, differentiation is usually not particularly difficult either from the gross appearance of the lesions or from other physical observations and laboratory data.

Tumors of epithelial origin should be considered from several points of view, namely, their malignancy or benignity, their extent of development, and their location. While an epithelial tumor may be malignant from its inception, many remain benign, or malignant changes only occur after a long period of time. There is therefore an overlapping of certain tumors in respect to malignancy and benignity, and one must consider this in giving a prognosis.

I purposely do not intend to spend much time on far advanced lesions. If they are viewed through the proctoscope the diagnosis is usually apparent, and in doubtful cases a biopsy will give the desired information. If the lesion is too high for visualization the patient will usually give a history of passage of considerable

amounts of blood and mucus, diarrhea or increasing constipation, and perhaps loss of weight and the presence of a palpable tumor mass. Occasionally the first sign of trouble is an acute obstruction, and in these cases one is at the mercy of circumstances. When such lesions are suspected, roentgen examination will almost invariably confirm the diagnosis. The prognosis in these cases is always serious, for, because of the advanced stage of the growth or of the general physical condition of the patient, only 50 per cent are suitable for radical operation. The only other condition that should be termed "advanced" is multiple polyposis, or, more accurately, multiple adenomatosis. The growths usually extend low enough to be visualized, and the x-rays will reveal how much of the bowel is involved. Almost certain development of a malignant growth or death from intercurrent disease is the fate of these patients, if untreated. Ileosigmoidostomy followed later by colectomy is the only satisfactory treatment. Tumors in the stump of the large bowel that is to remain are destroyed by coagulation or fulguration. Treatment of this type carries a high mortality and requires long hospitalization, but it is the only method offering a favorable prognosis.

PEDUNCULATED TUMORS

Since both diagnosis and prognosis and the accepted forms of treatment are quite well standardized in these advanced lesions, I want to call attention particularly to those cases in which the lesion is small, the prognosis more hopeful, and the methods of treatment less well agreed on. I will first consider lesions that can be visualized with the proctoscope—in most cases those occurring within the last 25 cm of the large bowel. The earliest symptom that may present itself with small tumors in this location is the passage of small amounts of blood and mucus. Unfortunately even this symptom may be lacking or is overlooked by the patient, and small lesions are often discovered only in the course of routine proctoscopic examination. The fact that in early lesions symptoms are absent or trivial is one of the tragedies of diagnosis in diseases of the bowel. In the diagnosis and prognosis of these small lesions I believe they are best divided according to certain physical characteristics, that is, into the flat lesions and the pedunculated lesions. The majority of the pedunculated lesions are in the beginning at least benign adenomas, or, as they are sometimes called, benign polyps. The term "polyp" I think is unfortunate, since it applies to any pedunculated tumor. The so-called fibrous polyp is usually an adenomatous tumor which through superficial infection and lack of blood supply due to torsion or attenuation of the pedicle has become fibrous, most of the glandular structure being destroyed. It would therefore be better to term this tumor a fibrosed adenoma. When it is seen in this stage of development one can feel sure that any danger of malignancy has

passed and that removal is necessary only for mechanical reasons. In an adenomatous tumor that has not reached the whitened stage of fibrosis, one cannot be sure that malignant changes will not occur or, in fact, may not already be present. The type of pedicle is of some importance in this respect. A thick-stalked tumor set close to the bowel wall and firmly fixed to the deeper layers carries greater potential danger of malignancy than one that has a long pedicle composed chiefly of mucosa. In either case these tumors should be considered at least as precancerous and removed. If microscopic examination reveals no sign of malignancy, there is no cause for further worry. If malignant changes have occurred, prognosis must be more guarded. Fortunately, the majority of these pedunculated tumors show a rather low grade of malignancy and, if there is a long pedicle, simple removal close to the bowel wall usually produces a permanent cure. If the tumor has a thick short pedicle there is greater danger of metastases, but if there is no invasion of the pedicle by the malignant cells the prognosis is still good. These tumors are best destroyed by electrocoagulation or fulguration, the destruction being carried well into the deeper layers of the bowel itself. The possibility of metastases must always be kept in mind, but, since these are unlikely, it is usually better to take this chance and be content with thorough local removal than to accept the operative mortality involved in subjecting the patient to a major surgical procedure.

The only other pedunculated tumor is the so-called villous tumor, characterized by an almost gelatinous appearing growth with many arborescent branches. These tumors have a tendency to become multiple, small tumors studding the wall round a larger one, much like the spacing of condylomata acuminata. The arborescent portion of the "parent" tumor will sometimes adhere to adjacent portions of the bowel wall, becoming organically attached to it. These tumors may degenerate into or be related to the so-called papillary carcinomas. Local recurrences following removal are not uncommon, and it may be necessary to destroy these recurrences several times before they are completely eradicated. They do not, however, form distant metastases. Their behavior is so like that of the condylomata acuminata that it would seem that the two conditions may be similar in character, condylomata acuminata being the result of some stimulation which occurs in squamous epithelium, and villous tumors the result of similar stimulation in the columnar epithelium of the rectum.

FLAT TUMORS

The flat tumors offer a different problem. Benign adenomas must necessarily in the beginning be but small slightly raised areas in the rectal mucosa, which gradually enlarge and become pedunculated. Therefore any flat lesion not more than 0.5 cm in diameter may be the beginning of a pedunculated adenoma. On the other hand the serpiginous type of carcinoma, which spreads by encircling the bowel wall like a rodent ulcer, also begins as a tiny elevated area in the mucosa. I have seen two slight button-like elevations on the bowel wall less than 0.33 1/2 cm in diameter, which on removal proved to be adenocarcinomas. Therefore even in the smallest flat button-like lesion, caution is necessary. A flat lesion as large as 0.5 cm in diameter is most likely a carcinoma, for, if the lesion were a simple adenoma, some evidence of pedunculation would most surely have occurred before the growth reached this width. In considering the flat tumors, two things must be taken into

consideration: their size and whether or not there is fixation to the submucous or muscular coats of the bowel. There is no way to make certain whether or not metastases have occurred, but metastatic involvement is quite likely when the tumor is fixed to the deeper structures. Almost without exception a fixed tumor calls for radical surgery. Fixation seldom occurs before the tumor is 0.5 cm in diameter, and for that reason the majority of tumors up to this size may be removed locally by coagulation or fulguration. On the other hand, tumors of 1 cm or more in diameter are usually fixed and require radical removal. Fixation is not, of course, the only criterion, and I feel that a flat type of cancer larger than 1 cm in diameter, regardless of whether or not it moves freely with the excursion of the rectal mucosa, should call for radical operation. The grade of malignancy of the carcinoma is of importance. The flat type cancer is usually of the higher grades, but regardless of this, with flat button-like tumors I would place the importance of fixation above that of the grade of malignancy.

In these small flat lesions, which are usually symptomless, it may sometimes seem ultraradical to insist on a major surgical procedure, but if there is fixation the physician should unhesitatingly insist on the most radical operation the patient's physical condition will permit. The chances of metastatic involvement of adjacent glands are too great to risk only local removal. When single small tumors occur above the field of proctoscopic visualization there are, more often than not, no symptoms that will make one even suspect the presence of a tumor. The earliest suggestive symptoms are the passage of a little blood or mucus, vague abdominal discomfort, symptoms of "irritable colon," or unexplained diarrhea. In these cases a roentgen examination following a barium sulphate enema and plates after evacuation and following the insufflation of the colon with air will sometimes reveal even these small lesions. I am sure, though that only too often the most careful roentgen examination will fail, and not until the lesion becomes more pronounced will it be found. Once suspected, examination should be repeated at regular intervals until one can be sure that no organic lesion exists. If a lesion so demonstrated proves to be a polyp with a definite pedicle and bleeding is absent or minimal it is permissible to adopt a policy of watchful waiting. If there is doubt, abdominal exploration should be undertaken at once, since the risk of laparotomy is much less than the chance of allowing a malignant lesion to remain. Since the probability of finding a small tumor in this unvisualized portion of the large bowel is not great, the prognosis for tumors in this region is not so good.

CONCLUSIONS

I think, then, that one is justified in drawing several conclusions concerning epithelial tumors of the large bowel.

1. Large epithelial tumors usually give symptoms definite enough to call attention to them. Their diagnosis either above or within the field of proctoscopic visualization is not too difficult and their prognosis is fairly certain.

2. Small epithelial tumors frequently give no symptoms. If low enough to be seen through the proctoscope they can be readily diagnosed, but above this area diagnosis is often impossible.

3. All epithelial tumors except the degenerated fibrous type offer some danger from malignant degeneration.

Some of these tumors, especially the flat button-like lesions, are frequently malignant from their earliest development

4 Because of this danger all epithelial tumors, no matter how small within reach of the proctoscope should be destroyed by electrocoagulation or fulguration, since this is a simple procedure devoid of danger. Small tumors with a definite pedicle, which lie so high in the bowel that they cannot be reached through a proctoscope and would require a laparotomy for removal should be observed periodically and removed at once if there is any sign of activity

5 In some cases as indicated in this paper, one is justified in simple local destruction of small tumors though definitely malignant. Caution should be used in advising this procedure, especially in the case of flat button-like lesions. If one is to apply this method at all in malignant cases, one must be careful not to extend its use too far because of its simplicity or the insistence of the patient. In a questionable case the physician must insist on more radical procedures

EXPERIENCE WITH ERGOTAMINE TARTRATE IN 120 PATIENTS WITH MIGRAINE

WILLIAM G LENNOX, MD

BOSTON

AND

THEODORE J C VON STORCH, MD

BROOKLINE, MASS

The use of ergotamine tartrate for the treatment of migraine headaches was first reported in 1926 by Maier¹. Since then, a number of articles have appeared recording the results of treatment in single or in small groups of patients. The only large group is that of Tzanck,² who treated 101 patients with favorable results in a large but unstated percentage. A year ago, one of us (W G L³) reviewed the literature and reported the results of parenteral injection in forty-five patients. Additional reports of treatment have appeared as follows: seven patients helped by oral administration (Podolsky⁴), headaches aborted by subcutaneous injection in fourteen of eighteen patients (Brock, O'Sullivan and Young⁵), and in each of nine patients (Logan and Allen⁶). Though the cases reported (including this series) number only 300, the dozen authors who have written on the subject are unanimous that the administration of ergotamine tartrate is effective in the great majority of patients in stopping migraine headaches.

Our experience with ergotamine tartrate now covers nearly three years and a group of 120 migraine patients

From the Department of Neurology of the Harvard University Medical School and the Neurological Unit Boston City Hospital aided by a grant from the Josiah Macy Jr. Foundation

have been treated by us or on our advice.⁷ These have been given a total of several hundred injections for as many headaches and have ingested thousands of tablets.⁸ In enumerating the results, we shall first detail the effects of the first administration of ergotamine and then the results of continued treatment of a smaller group.

The patients in this series all suffered from severe periodic headaches. In addition, they had one or more of the following satellite symptoms: hemicrania, nausea or vomiting, visual disturbances, vasomotor disturbance and malaise. They failed to obtain relief from other drugs or treatment, and each gave a history of migraine in other members of the family. Twenty-three of the patients were males and ninety-seven females.

RESULTS

Of the 109 patients who received the drug by intravenous, intramuscular or subcutaneous injection the result of the first administration was abrupt and complete relief in 90 per cent, slight or temporary relief in 4 per cent, no benefit in 4 per cent and headache made worse in 2 per cent. Of the eleven patients who received medication only by mouth, the first trial was followed by relief in 82 per cent, while 18 per cent were made worse.

Of the whole group of 120 patients, 89 per cent experienced abrupt and complete cessation of the headache with the initial use of ergotamine. The cases in which the treatment was given were chronic, and other forms of therapy had not helped. No other drug or treatment which had been reported in the literature has been effective in such a high proportion of patients with migraine. The results, therefore, are dramatic and conclusive. In ergotamine tartrate, the physician possesses a nonsedative drug which almost invariably aborts even the worst of migraine headaches.

Furthermore, the beneficial action of ergotamine seems to be specific, or nearly so, for headaches of the migraine type. Of forty-five patients with headaches from other causes, only seven noted definite improvement after the intravenous injection of the drug. Indeed, intravenous injection in eighty-three non-migrainous subjects produced headache in six.

Results of repeated treatment are of more importance than those of the initial administration. In general, patients responded to subsequent injection as they did to the initial trial. There were, however, five patients who later failed to obtain the relief experienced at first. Nineteen patients have been followed for more than a year, a few of these having what might be called a "migraine status" with almost continuous headaches. In the others, the attacks before treatment were frequent and severe so that the entire group of nineteen represents a much more than average degree of intractability. All but one of these patients has obtained relief with each injection of ergotamine. In most of the patients the interval between attacks has not been significantly altered, in a few, especially those most severely affected, the headaches have recurred at more frequent intervals, in a number, the attacks have been more widely spaced. In the entire group of 120 patients, ten have had unusually long periods of freedom since treatment was begun. On the whole, we find that headaches aborted by ergotamine tend to recur at shorter intervals, especially in the first few weeks or months of treatment.

7 Ten patients were treated by our colleague Dr. Stephen Maddock.
8 The ergotamine tartrate (Gynergen) used in this investigation was supplied by the Sandoz Chemical Works, Inc.

The joy of the patient over his miraculous relief from headache is often tempered by certain unpleasant symptoms which he may experience. Nausea occurred in 77 per cent and vomiting in 60 per cent of eighty-nine cases in which such a record was made. In a group of thirty-four patients not subject to headaches who received intravenous injections of 0.5 mg., nausea occurred in 50 per cent and vomiting in 24 per cent. After obtaining relief from headaches by the use of ergotamine, most patients experience a sense of fatigue and lassitude, this being an accentuation of the sensation experienced after spontaneous recovery. A few patients complained of muscular pains which wore away with exercise, or of paresthesias or a sense of substernal or precordial oppression. These various symptoms were not experienced by nonmigrainous patients who were given intravenous injections of the drug. Rarely, gastro-intestinal or other symptoms are sufficiently distressing so that the patient prefers the headache to the treatment.

With serious or permanent ill effects we have had no experience. Because ergotamine raises the blood pressure, caution should be exercised in administering it to patients with arterial disease. Pregnancy is not an absolute contraindication according to the evidence collected by Barger⁹ for ergotamine, even in toxic doses, may not produce abortion. In one patient Schimmel¹⁰ injected 25 mg. in a period of thirteen days without causing an abortion. Excessive and long-continued use carries the danger of ergotism. However, the daily injection of 0.5 mg. for a period of months, and the daily ingestion of from 10 to 15 mg. for more than a week has not produced suspicious symptoms.

THERAPEUTICS

When ergotamine tartrate is injected, the usual dose is 0.5 mg. (the contents of a 1 cc. ampule). In some patients a half or even a third of this dose may be effective and should, therefore, be used. One patient required for relief the injection of 1 mg. Only rarely is a second injection required. We principally made use of the intravenous route because experimental observations were being carried on concurrently. This route has the advantage of giving more prompt relief (in from fifteen to thirty minutes instead of in from forty-five to ninety minutes after subcutaneous injection) and more certain relief and there is no pain due to the injection. Intravenous injection, on the other hand, is more likely to be attended by unpleasant symptoms, such as nausea, vomiting or muscle pain. Intramuscular injection is a satisfactory compromise. Our more intelligent patients have been supplied with hypodermic needles and syringes and have managed their own injections.

In the cat, only 30 per cent of ingested ergotamine is absorbed.¹¹ In patients the presence of nausea and vomiting is an added obstacle to absorption from the intestinal tract. This probably explains the relatively slight benefit resulting from the use of tablets taken by mouth. However, in milder cases (as represented by our group of patients who received only oral treatment) beneficial results may be obtained from the 1 mg. tablets. From two to five tablets may be given when the headache begins, followed by one or two at

hourly intervals until 9 or 10 mg. has been taken or relief has been obtained. Two hours or more may elapse between the ingestion and relief. If nausea and vomiting are violent, atropine sulphate in 0.5 mg. doses may be given in addition to the ergotamine. The enteral and paracental routes may be used simultaneously. A 0.5 mg. ampule of ergotamine costs at the present time 30 or 40 cents. On the basis of the ergotamine content, the tablets for oral use cost approximately only one tenth as much. On the basis of therapeutic results, however, we believe that a 0.5 mg. ampule, given intramuscularly, is worth much more than the equally priced five 1 mg. tablets taken orally.

The prevention of headaches by either injection or ingestion of ergotamine may be attempted if the time of the onset of the headaches is predictable. Headaches may thus be postponed or ameliorated but not, except perhaps in mild cases, prevented. It should be emphasized that while ergotamine tartrate is valuable in aborting individual attacks, its use should not take the place of efforts to find and remove the cause or causes of the condition.

THE MECHANISM OF ACTION

The mechanism by which ergotamine tartrate affords relief from migraine headache has not been satisfactorily explained. The occurrence of vomiting appears to bear no direct relationship to the obtaining of relief. Following an intravenous injection, both patients and controls have an increase in systolic and diastolic blood pressure and a decrease in pulse pressure and pulse rate. Investigations thus far carried on in our laboratories indicate that the cerebrospinal fluid pressure is increased, though the rise is less in migrainous than in nonmigrainous patients.¹² The circulatory changes are at their height within a few minutes after the intravenous injection, whereas relief from headache does not begin for from fifteen to thirty minutes. Ergotamine increases the blood flow through the brain¹³ and arm of man and causes concentration of the blood.¹⁴ In the cat, it has no consistent effect on the arteries of the pia but constricts those of the dura and the skin.¹⁵

These results do not in themselves seem adequate to explain the relief obtained from migraine pain. Most authors have suggested that ergotamine paralyzes the motor endings of the autonomic nerves, thus relieving presumed arterial spasm and pain. It might, however, act directly on the sensory fibers of the nerves, especially those supplying the arteries of the brain or dura. The relief obtained from pruritus following the administration of ergotamine is a strong point in favor of the effect on the sensory nerves. However, if this were the case, ergotamine should relieve other types of headache associated with dilatation or contraction of the cerebral arteries, such as headache following an injection of histamine, but this it does not do.

CONCLUSIONS

Ergotamine tartrate was used in 120 patients with migraine headache. The initial trial resulted in abrupt and complete relief from the headache in 107 of these patients. Nineteen patients have used ergotamine for more than a year, and all but one have obtained relief

on each of the repeated occasions in which ergotamine has been used. In some patients a tendency for the headaches to recur at more frequent intervals or the appearance of unpleasant accompanying symptoms limits the use of the drug. The administration is by intravenous or subcutaneous injection. Ingestion is relatively ineffective. The mechanism by which relief is obtained is as yet unknown.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY ULTRA- VIOLET RADIATION

JOHN S. COULTER, M.D.

AND

HOWARD A. CARTER, B.S. in M.E.
CHICAGO

This study was undertaken to determine the value of sunlight and artificial radiation in the treatment of pulmonary tuberculosis. The members of the staff of the City of Chicago Municipal Tuberculosis Sanitarium believe that if ultraviolet radiation is of value in the treatment of pulmonary tuberculosis it should not fail in all the active forms and should not be limited in its usefulness only to the least active. In their opinion, if ultraviolet radiation should be used only in selected forms of chronic pulmonary tuberculosis it would be impossible to determine whether ordinary treatment in a sanatorium produces an improvement or whether the ultraviolet radiation is a factor in this improvement. It was decided therefore that, if ultraviolet radiation is of value in the treatment of pulmonary tuberculosis, it should show some definite results in three months' treatment in active cases. These patients should have no fever and no hemoptysis and should be able to walk or ride in a wheel chair to the room where ultraviolet treatment is given.

Karsner¹ recently stated that, in the evaluation of methods used in physical therapy, the value of the treatment is not to be measured by the opinion of the physician but rather by the facts he can demonstrate. In this study we have endeavored to follow the statistical method as given by Karsner to decrease whatever errors might arise by the summation of the opinions of interested observers.

In order to obtain facts and not opinions, all the members of the staff of this institution cooperated. The patients were referred to the physical therapy department for ultraviolet irradiation by the physicians in charge of the wards, the blood examinations and roentgenograms were made before and after the three months' course of treatments. The ultraviolet irradiation was given under our direction according to the Rollier technic, the quality and intensity of the radiation were determined by one of us (H. A. C.) and the results were judged by the clinical staff.

Dr. Sweeney, in charge of the laboratory of the Municipal Tuberculosis Sanitarium, examined the reports of the blood examinations and the roentgenograms made before and after ultraviolet irradiation and commented on them without being informed as to the details of each case or the treatment given. The clinical results were recorded on the patient's clinical charts.

by the ward physicians. It is believed that this method avoided the giving of favorably or unfavorably prejudiced opinions.

In order to check our data further, a series of patients who did not receive ultraviolet treatment were used as controls.

SOURCES OF ULTRAVIOLET RADIATION

Not only is the sun regarded as the source of all energy, but it is also the best of all sources of radiation for ultraviolet therapy. However, owing to climatic conditions, sunlight is not always available for therapeutic use. For example, Tonney, Hoeft and Somers² have shown that in the downtown loop district in Chicago during the months of October, November, December, January and February, the ultraviolet content of sunshine is seldom strong enough to provide a minimum erythema dosage. They have also shown that sunshine in that district contains much less ultraviolet radiation than at points outside the congested district, such as the south side of Chicago near Lake Michigan or the Indiana dunes district. Hence, if therapeutic ultraviolet radiation is desired in the winter-time, Chicago physicians are obliged to use some form of artificial radiation instead of natural sunlight. Solariums made of special glass would probably not suffice. In this work we employed artificial radiation during all the months of the year except three—June, July and August. Our source was a large carbon arc lamp, 60 ampere capacity, with C carbons, the cores of which were impregnated with iron, nickel, aluminum and silicon. Polymetallic carbons make the ultraviolet component of the radiation richer than it would be with carbon alone. The spectral intensity curve for carbons impregnated with metals is given by Coblentz.³

MEASUREMENT OF ULTRAVIOLET RADIATION

Ultraviolet Meters—Fairly accurate instruments have been developed recently for measuring the ultraviolet component of artificial radiation emanating from quartz mercury arc (high vapor pressure) lamps and from the carbon arc. One convenient instrument consists essentially of a light-sensitive cell mounted behind a glass filter which permits radiant energy of wavelengths between 2,500 and 4,000 angstroms to pass. This light cell is connected to a sensitive micro-ammeter, and when the cell is in the presence of radiant energy a current is generated, which is measured by the ammeter. This meter is available in two forms—an indicating and a recording type. It appears to be quite satisfactory for measuring radiation from mercury vapor arc (high vapor pressure) lamps and from the carbon arc. This meter is not recommended by the manufacturer for measuring the ultraviolet radiation in sunlight.

Another instrument we employed consisted of a light-sensitive photocell with a direct current rectifier for energizing it, a relay tube and an indicator. The principle of operation is that the photocell, sensitive to certain bands of waves in the light spectrum, allows a minute electric current to pass when it is exposed to radiation. This current is proportional to the ultraviolet radiation energy in the particular band of the spectrum that is used. The small current charges a small condenser, which is connected in parallel to a relay tube.

Aided by a grant from the Council on Physical Therapy to the City of Chicago Municipal Tuberculosis Sanitarium.

² Tonney, F. O., Hoeft, G. L. and Somers, P. P. Loss of Actinic Intensity in Urban Sunshine Due to Air Pollution. J. Prev. Med. 4: 139 (March) 1930.
³ Coblentz, W. W. Sources of Ultraviolet and Infra Red Radiation Used in Therapy. J. A. M. A. 103: 183-188 (July 21) 254-257 (July 28) 1934.

Every time the condenser is fully charged, the relay tube "spills over," discharging the condenser and sending an impulse to the recorder. The stronger the ultraviolet energy, the faster the condenser charges and discharges. The counter is calibrated in units of radiation energy. The device used was an experimental model and, as such, did not give the satisfaction that might have been expected in a perfected commercial product. One objection to this unit was that it was not practical to measure the entire ultraviolet content of the spectrum because the photocells responded only to certain bands of waves. This unit therefore, did not render complete satisfaction as a measuring instrument of the ultraviolet energy of sunshine.

The third meter was of similar construction making use of a photo-electric cell microgalvanometer, two transparent filters and a battery. Two readings were taken each time the source was metered—first with one filter in front of the tube and then the other. Finally, by means of an empirical formula the ultraviolet energy was calculated in units of radiation energy. The meter was not used for measuring sunlight.

Another method was the use of chemically pure zinc sulphide mixed in a small mortar with a few drops of solution of zinc acetate and ground to a smooth soft paste. This paste is pressed flat between a piece of glass and a piece of transparent quartz. The glass and the quartz plate are held together by rubber bands and exposed to the sunlight with the quartz uppermost. After an exposure of one, two or three minutes, the change in color is matched with the color chart.⁴ This method requires an experienced eye to judge the change in hues, since the various shades of gray are difficult to distinguish and was discarded because it was inconvenient for the ordinary nurse giving these treatments to use it.

Another meter operating on the color-changing method was employed. This photochemical ultraviolet meter consists of a solution of leukocyanide of triphenylamine dye sealed in a transparent tube. The tube is mounted in a light-tight box, which can be opened and exposed to the sunshine. The dye is colorless in the dark but turns pink temporarily when exposed to short wavelength ultraviolet radiation. The pink is reduced to a neutral gray by insertion of green filters of different densities. These are calibrated in intensities from 0 to 9 and are calibrated arbitrarily in terms of microwatts per square centimeter to indicate the intensity and the corresponding time of exposure necessary to produce a minimum perceptible erythema. Since this unit depends on the ability of the observer to distin-

guish a neutral gray and also on his ability to time the intervals between readings correctly, it was not considered a very satisfactory instrument.

Heliotherapy—All the aforementioned instruments were used at one time or another in an attempt to measure the ultraviolet component of sunlight, but they could not be relied on for that purpose. The photo-electric cells, for example, were sensitive to infra red radiation and, on many days when the sky appeared clear, the reading indicated that there was less ultraviolet energy than on a foggy or hazy day. The instruments composed of photo-electric cells were discarded as inaccurate for measuring the ultraviolet radiation in sunlight. The color-changing instruments were too difficult to manipulate and read. Thus, many errors were introduced in the observations. Although the photo-electric cell meters were inaccurate, they were used and certain observations of value were recorded that facilitated the work. For example, it was observed that in the course of a forty minute treatment, the radiation intensity of the sun varied widely owing to such factors as the sun's change of position, dust, clouds and visibility, and usually the conditions necessitated a change in the time of exposure which would be quite different from that contemplated at the beginning of the treatment. These changing atmospheric conditions introduce obstacles which make the control of dosage factors quite impossible. A meter that would faithfully record all the therapeutically useful ultraviolet energy in sunlight and at the same time integrate the energy with respect to time would be the ideal instrument.

The large carbon arc lamp employed in this investigation was tested for intensity with a sensitive photo-electric cell and a galvanometer. The readings were quite accurate since the meter was calibrated to measure the ultraviolet radiation from a carbon arc and are given in table 1.

DOSAGE

Our experience in these cases confirms Laurens's⁵ statement that it is becoming more and more evident that aside from knowing whether a lamp emits sufficient ultraviolet energy to be of clinical value and knowing about how long an irradiation with it will produce a desired degree of erythema, a modern dosage meter in practical heliotherapy has no value. The important consideration is the individual patient and his reaction, and the dosage is modified accordingly. As the erythematous response is the only physiologic reaction that can be easily judged for each patient, our dosage technic was the use of a modified Rollier method to secure a faint erythema over increasing areas of the body starting at the feet.

The feet were uncovered the first day for five minutes for exposure to the direct sunlight. On the second day the legs to the knees were exposed for five minutes and the feet ten minutes. The third day the thighs were uncovered for five minutes, legs ten minutes and feet fifteen minutes, fourth day abdomen five thighs ten, legs fifteen and feet twenty minutes, fifth day chest five, abdomen ten, thighs fifteen, legs twenty and feet twenty-five minutes. These exposures were given in the sunlight to both the front and the back of the body in all instances once daily. The time stated represents half of the total exposure, that is, the total for the feet the first day was ten minutes. With

the carbon arc lamp the exposures were started with two minutes to the feet and increased one minute daily as previously described. As soon as the whole body had received a faint erythema from the daily sunlight or carbon arc treatments, the irradiations were given every other day.

The pigment produced in the skin by sunlight and the carbon arc are nearly alike—a brown to red brown. Many observers believe that an increased production of pigment means an increased tendency to healing. Our sixty patients showed increased pigmentation of the skin, but this bore no relation to the improvement or lack of it.

DANGERS

An analysis of the cases treated with ultraviolet radiation at the Municipal Tuberculosis Sanitarium shows that the ill effects which may follow such treatment have been exaggerated, provided the dosage of ultraviolet radiation is carefully given. The generally listed dangers are

1 *Dangers of Reactivation of a Quiescent Disease*—Many of our patients came with the statement that their physicians had told them that they should never expose their chests to ultraviolet radiation as it would make the pulmonary condition worse. There are no data in the literature to substantiate such a statement. All our patients were exposed by the Rollier technic until the whole body was exposed. In no case was there any reactivation of the pulmonary disease.

The average penetration of the radiant energy from the part of the spectrum used in ultraviolet irradiation with sunshine or a carbon arc lamp is far ultraviolet, 0.1 to 0.5 mm, near ultraviolet, 0.5 to 1 mm, visible light, 1 to 5 mm, and near infra-red, 5 to 10 mm. Therefore the penetration of ultraviolet rays is so slight that it can have no direct action on the lungs. It is known that ultraviolet radiation between 2,900 and 3,130 angstroms activates ergosterol in the skin so that an active antirachitic substance is formed. This does not mean that ultraviolet radiation may not have other beneficial effects or potentialities for harm. But the exposure of the chest in general ultraviolet treatment can have no harmful effect unless there is an overdose of ultraviolet radiation, and the same effect could be produced by an overdose on the other parts of the body with the chest covered.

Sonne's work on the action of the spectrum of sunlight and the carbon light shows that during irradiation with the highest endurable intensity of visible energy the temperature of the skin is 43.8 C (110.8 F), at a depth of 0.5 cm with visible rays it is 47.7 C (117.8 F). There would be a real danger in cases of pulmonary tuberculosis if the patients were exposed to sunlight at low levels during the noon hours or too near a carbon arc lamp, but our patients were exposed to sunlight in the earlier morning hours and at a distance of 6 feet (183 cm) from the carbon arc, so there was no possibility of producing the rise of temperature subcutaneously, as was shown when patients were exposed to the highest endurable intensity of radiant energy.

2 *Danger of Disseminating Infection*—There are reports in the literature of the dissemination of pulmonary lesions by ultraviolet radiation used in the treatment of pulmonary tuberculosis. Our series of cases showed no such unfavorable results. Some of the patients became worse and the disease spread but it was not believed by the ward physician that the ultraviolet irradiation had disseminated the infection.

3 *Hemoptysis*—In our series four patients showed hemoptysis (blood-streaked sputum). All these had had this symptom previously, and the physician in the ward would not attribute it to the ultraviolet irradiation. In our analysis of the literature only eight of the seventy observers of the use of ultraviolet radiation reported hemorrhages, and these observers did not give an accurate statement of the dosage administered. Our conclusions are that carefully given ultraviolet radiation entails no dangers from hemoptysis.

4 *Progressive Tuberculosis and Focal Reactions*—Observers have reported in cases of uncomplicated pulmonary tuberculosis with fever, although not rapidly progressive, the development of focal reactions during ultraviolet irradiation. Mayer⁶ states that (1) uncomplicated active pulmonary tuberculosis with high temperature even though not rapidly progressive is a contraindication to ultraviolet irradiation and that (2) in uncomplicated cases of pulmonary tuberculosis in which the disease process is not yet quiescent and may be accompanied by slight or moderate elevation of temperature, ultraviolet irradiation if employed at all should be used with the greatest caution. In our cases ultraviolet irradiation was used only in cases in which there was slight fever or none at all, and, if the temperature went to 100 F, treatment was stopped until it returned to its former level. Therefore there were no focal reactions in this series.

RESULTS

Underwood⁷ gives Kayser of Vienna the credit for being the first to use artificial light for pulmonary tuberculosis, in 1902. An analysis of the literature since that time shows that there is an extraordinary diversity of opinion as to the merits of this treatment. An analysis of the literature shows that, of seventy competent observers, forty-six had favorable and twenty-four obtained poor results or none at all with ultraviolet radiation in the treatment of pulmonary tuberculosis. The detailed analysis is not given here because of lack of space but will be furnished on request.

Blood Examinations—It was believed that the information that could be obtained from the examination and correct interpretation of the blood was an objective fact that could be used as an aid and as a substitute for personal opinion in evaluating the effects of ultraviolet radiation in these cases of pulmonary tuberculosis.

Red Cells and Hemoglobin—In a review of the literature on the effect of ultraviolet radiation on the blood out of twenty-seven reports fourteen investigators found the red cells and hemoglobin value increased and thirteen found no effect following general ultraviolet irradiation.

In our series of cases there was no suggestion that ultraviolet radiation had any influence on red cells and hemoglobin in cases of advanced pulmonary tuberculosis.

The red blood cells showed an increase in seventeen and a decrease in thirteen of the thirty cases of pulmonary tuberculosis treated. The average increase was 485,000 and the average decrease was 397,000. In the control series fourteen showed an average increase of 594,000 and sixteen showed an average decrease of 407,000.

6 Mayer, Edgar. *Clinical Applications of Sunlight and Artificial Radiation*. Baltimore: Williams & Wilkins Company, 1926.
7 Underwood, E. A. *Treatment of Tuberculosis by Light*. Brit. J. Tuberc. 26: 178 (Oct.) 1932.

The hemoglobin value in these cases showed in twenty cases an average increase of 82 per cent and in ten cases an average decrease of 36 per cent. The control series showed sixteen cases with an average increase of 75 per cent and fourteen cases with an average decrease of 9 per cent.

In the thirty cases treated following thoracoplasty, fourteen showed an average increase of red blood cells of 598,000 and sixteen an average decrease of 39,000. Twenty of these cases showed an average increase of 12 per cent in the hemoglobin value and ten an average decrease of 45 per cent.

White Cells. It was decided that a simple estimation of the number of the various types of white cells would not give sufficient information on the action of ultraviolet radiation in pulmonary tuberculosis. It was also difficult to select one method of estimation of the ratio of the white cells as a measurement of the effect of ultraviolet radiation on the activity in pulmonary tuberculosis. Therefore, in the comparison of the white cell

TABLE 2—*Clinical Results of Ultraviolet Irradiation in Pulmonary Tuberculosis*

Condition	Ultraviolet Irradiation		Controls	
	Number of Patients	Percentage	Number of Patients	Percentage

Arrested	9	30.0	25	34.6
Not improved	5	16.7	11	13.6
Total	30		81	

counts, three methods of estimation were considered in evaluating the effect of the ultraviolet radiation on the activity of the pulmonary lesion as measured by the blood examination.

1 In Medlar's concept of the leukocytic picture the monocyte is considered as the white cell forming the primary tubercle and taking a large part in the repair of tuberculous lesions. The neutrophil is the chief cell in the formation of tuberculous abscesses or in enlarging ulcers or cavities. The lymphocyte is the predominating cell only when the lesion is healing. When the neutrophils number over 5,000 per cubic millimeter of blood, it is believed that the tuberculous lesions are undergoing abscess formation or that the ulcerous lesions are extending. When the monocytes number over 700 per cubic millimeter, that is evidence of the formation of new tubercles. If the lymphocytes number over 2,000 per cubic millimeter, healing is in progress.⁸

2 According to Cunningham, if the monocyte-lymphocyte ratio is computed, an increase of monocytes is an index of dissemination of the disease, and an increase of lymphocytes is an index of resistance to the disease. The normal average ratio of monocytes to lymphocytes is 1:4. It is believed that, when this ratio approaches normal or reaches values below normal, this is a valuable indication that the infection is being successfully withstood. An increasing ratio indicates that the patient is losing the fight.⁹

3 The Schilling differential count was interpreted according to Schilling's principle that the stab cells increase first in cases of infection and that if they constitute more than 3 to 5 per cent of the peripheral blood, a toxic element is retarding the normal development of myelocytes and juvenile cells into mature segmented neutrophils. This is known as a "shift to the left," an expression originally used by Arneeth to mean an increase in neutrophils with unsegmented nuclei at the expense of the segmented or mature forms. Schilling also believes that in a severe infection the bone marrow is overstimulated, thus causing the myelocytes to develop more rapidly, and the juvenile forms are poured into the circulation.¹⁰

These three theories were considered in evaluating the effect of ultraviolet radiation on the white blood cell picture in cases of pulmonary tuberculosis. Our compiled statistics show that this form of treatment produced no uniform effect on the white cell count.

Most authors state that ultraviolet radiation stimulates lymphocytosis in men and animals. In our sixty cases of advanced pulmonary tuberculosis this occurred only when the condition was improving, and an increase in lymphocytes occurred when the lesions were healing either with or without ultraviolet radiation.

CLINICAL RESULTS

The clinical results, as listed in table 2, in our opinion showed no definite benefits derived from the use of ultraviolet radiation in the treatment of active pulmonary tuberculosis or in these cases following thoracoplasty.

In cases of thoracoplasty with delayed wound healing, local ultraviolet irradiation with a carbon arc lamp increased the growth of healthy granulation tissue and the tendency to epithelization.

CONCLUSIONS

1 Ultraviolet radiation of the described intensity in doses sufficient to produce a mild erythema and subsequent pigmentation produced no beneficial effects in cases of active pulmonary tuberculosis or in cases following thoracoplasty.

2 Near a large city the changing atmospheric conditions introduce obstacles that make the selection of the dosage factors impossible in heliotherapy.

3 The generally listed dangers following ultraviolet irradiation in cases of pulmonary tuberculosis have been exaggerated, provided the dosage of ultraviolet radiation is carefully regulated.

4 In this series of cases there was no suggestion that ultraviolet irradiation had any uniform effect on the red blood cell count, the hemoglobin value or the white blood cell picture.

PSYCHIATRY IN GENERAL PRACTICE

WITH SPECIAL REFERENCE TO THERAPY

MENAS S GREGORY, M.D.

Professor of Psychiatry New York University College of Medicine
NEW YORK

Our conceptions of psychiatry have undergone considerable evolution during the past quarter of a century. The term psychiatry is now used in a very broad sense, embracing all kinds of mental disease, mild or grave, transitory or protracted, benign or malignant, in fine, every variety of mental disorder or abnormality, including personality problems, behavior disorders, child guidance and problems of mental hygiene, social maladjustment, crime and delinquency.

In the present discussion, while using the term in its broader sense, I shall confine myself to a few psychiatric problems of importance and especially to those which serve as a background for the discussion of psychotherapy, which is of the utmost importance in general practice.

To avoid the use of psychiatric technicalities and for the sake of brevity, I shall refer to several well recognized general groups, namely, the affective or emotional group, the schizophrenic group, the organic group, the toxic infective and exhaustive group and the psychopathic personality and neurotic group.

THE AFFECTIVE OR EMOTIONAL GROUP

The disorders of the first group, the affective, may be described as emotional disturbances closely patterned after the emotional swings or upsets in normal life. They are of a benign character and, when uncomplicated, always end in complete recovery. Many such patients never require hospitalization.

The manic depressive psychosis is the most important disorder of this group. This is a very common malady, ordinarily and formerly known as mania and melancholia, and now known as manic depressive psychosis. It is a constitutional disorder which manifests itself in longer or shorter attacks of excitement or depression and which has a marked tendency to periodicity. It is equally frequent among the two sexes and may occur at any age. The chief symptoms of the depressed phase are emotional depression, psychomotor retardation, difficulty of thinking and various subjective feelings of inadequacy and self abnegation, self debasement and reproach, with many other accessory symptoms.

The fully developed attack of manic depressive psychosis, whether of depression or excitement, is quite obvious, usually requiring hospital treatment, and is therefore not pertinent to the present discussion. Manic depressive psychosis, however, may and frequently does occur in very mild forms. These mild depressions and excitements are as common, one might say, as gastric disorders or the common cold. Speaking now of the depressions, these may in some cases, because of their extreme mildness, closely resemble the moodiness and emotional swings of normal life. The analysis of the symptoms, however, will clearly demonstrate that such is not the case.

Every physician has frequently seen patients who complain of a general tired feeling, of inability to interest themselves in their daily routine, of difficulty of concentration, of a subjective feeling of inadequacy and insufficiency, of lack of pleasurable thoughts and

of a feeling of hopelessness and helplessness, bordering on despondency. In these cases the symptoms are generally associated with some sluggishness of various bodily functions, which may in many instances be the main occasion for seeking medical aid. The mental symptoms are usually quite marked early in the day, particularly on awakening, and in the afternoon and evening they become somewhat ameliorated. Some of these patients attribute their symptoms to some vague bodily conditions and others to definite environmental factors, such as financial reverses or the death of a near relative or similar emotional stresses.

It must be admitted that a condition of this kind can easily be misunderstood or even overlooked, first because, despite their complaint, these patients still are capable of carrying on their routine work to some extent, they generally do not give evidence of any tangible somatic disorder and, above all, because of the strong desire on the part of the physician (who is not psychiatric minded) to interpret these symptoms on the basis of physical or environmental factors. It is not uncommon to meet a patient of this kind who has received a careful physical examination and has been told that there is nothing the matter with him.

These conditions, as I have already stated, are very common, and failure to recognize their true character frequently leads to serious difficulties, such as business and family complications or aggravation of the malady. But suicide, of course, is the most dreaded complication in these cases. Despondency and loss of the joy of life are an integral part of the group of manic depressive disorders.

I wish to emphasize the accident of suicide for the obvious reason that it is fraught with unpleasant consequences for the physician as well as for the family. Most physicians are surprised to learn that suicides or attempts at self destruction are more common among patients with a mild depression than among those with severer attacks of melancholia. While it is true that the suicidal impulses are stronger and more constant in the severer types, the psychomotor retardation (which means physical and mental sluggishness, marked indecision and inertia), the most characteristic symptom of the disease, often prevents the patient from carrying these impulses into action. In milder cases, whenever the suicidal wave overwhelms the patient, though it may come at rare intervals, nevertheless, because of a lack of marked retardation, inertia and indecision, the patient is capable of carrying it into effect.

A great majority of the suicides reported in the daily press as of patients suffering from so-called mild nervousness are of this kind. A number of years ago, suicide was a misdemeanor, and all persons who attempted it in New York were placed under arrest and brought to the prison ward of Bellevue Hospital. Most of them suffered from mild depressions of the manic depressive type.

It is my custom to impress on students this general rule, i. e., to anticipate a tendency to self destruction in all types of mental depression, and to be particularly careful in mild cases as well as in the beginning of an attack of melancholia or during convalescence and just before recovery from such an attack. It is a matter of clinical observation that even in hospitals a large proportion of suicides occur at these times, for the reasons already stated, and, further, that since the patient appears almost normal or recovered at such times there is apt to be less watchfulness on the part of even the physicians and the nurses.

Another fact that makes recognition of these mild depressions as mental diseases extremely difficult is that sometimes a patient refers his symptoms to a bodily organ which may have some special significance for him. This may be due to an inferior function or to a fixation of interest often going back to childhood experiences. Some patients refer all these symptoms to the cardio-circulatory function and complain of serious heart trouble, others refer them to the gastro-intestinal tract, and occasionally some complain of rheumatic, neuralgic, neuritic and other familiar disorders.

An elderly woman of high social station has been suffering for some years from periodic attacks of what she terms "heart trouble" and for which she has been treated by various physicians. These attacks last for from a few days to several weeks during which she retires to her room, keeps aloof from the members of her family and becomes morose, irritable and despondent. She however, ascribes all her symptoms to the cardiac difficulties, complaining of vague precordial distress. Her physician, now dead, to whom she had been referred as one of the outstanding consultants of his time, recognized the psychogenic nature of the illness, stating that "although she has a slight cardiac murmur, it is not of such a character as to cause the discomfort or the distress complained of." There is also a history in this case of sudden overactivity and exuberance, psychic as well as physical, from time to time. She has a daughter who suffers from the circular type of manic depressive psychosis.

In other words, this patient, who suffers from mild attacks of depression has been treated for some years for cardiac disease, because she projects the symptoms of an essentially psychic disorder of mild character into a special organ, namely, in her case, the heart.

Alcohol plays a curious and interesting part in connection with these mild attacks of depression. At times alcohol masks the disorder in some patients who associate their attacks with drinking. Many of these persons are regarded as "dipsomaniacs" and treated as such. Some years ago, in a paper entitled "Transient Attacks of Manic Depressive Psychosis," I reported many cases of this kind from the alcoholic service of Bellevue Hospital. In these cases alcohol is an incident to the underlying manic depressive depression.

A very interesting fact is that alcohol in some of these cases serves to shorten these attacks. As a striking example, I may cite the case of a physician, who is now dead. He was subject to attacks of periodic drinking which were called dipsomania and would last for from two to five weeks, after which he abstained from alcohol. His illness was finally recognized as a mild manic depressive disorder, with alcohol as an incident and treated accordingly. These short attacks, however, associated with alcohol, continued to recur, although not as frequently as formerly. But during several of the periods of depression he failed to use alcohol at the inception of the depression. The latter attacks, unassociated with alcohol, lasted for prolonged periods (from six to nine months).

In this case and in many similar ones that I have observed, the use of alcohol evidently helped to shorten the attacks. Possibly the well known psychologic effect of alcohol, by bringing about mental relaxation, ease and flight from reality, prevents the formation of a superstructure of psychogenic fears and fancies which retard recovery from the depression. It should not be inferred, however, that the administration of alcohol in these depressions is to be recommended to shorten

the attacks. It is most probable that the effect of alcohol in the cases described is in the nature of an instinctive compensatory psychotherapeutic measure operating on a certain type of personality.

A few words on the opposite phase of the same disorder, namely, exhilaration instead of depression. The attack of exhilaration with overactivity, fluency in thinking and talking, undue optimism, a subjective feeling of physical and mental well being and exuberance—symptoms diametrically opposite to the depressive phase—may very closely resemble the mood seen in normal persons who are energetic, jolly, talkative, meddlesome and superficially efficient, the "Citizen Fixit" type.

This disorder can readily be recognized if the personality traits just enumerated suddenly appear in a man who is usually quiet and retiring, and particularly when such a person carries his activity, as he will eventually, into more or less irresponsible conduct, coming into conflict with conventions, surrendering himself to various excesses, such as excessive drinking, sexual blunders and reckless extravagance. This type of patient is more of a source of danger to his family and others than is the depressed type, who is mostly bent on self destruction. To permit these patients to follow their own devices may result in disastrous consequences to reputation, virtue, fortune and health.

It should be observed that in both of these types a superficial examination may not disclose the true state of affairs as to the mental condition, as patients suffering from this type of disorder are capable of momentarily controlling themselves to the degree that even an experienced psychiatrist is at times deceived. A safe and wise rule to adopt in order to avoid errors in examination and diagnosis in these cases is to give serious attention and weight to the information furnished by the family and friends and not to depend entirely on a short personal examination at one time.

While dwelling on the affective or emotional group I must also mention briefly the so-called reactive or situational disorders, which are so common in general practice. These are also benign emotional disturbances with a symptomatology which represents flight from realities and conflicts of life. These patients have a neurotic or psychopathic make up and naturally the clinical manifestation of the mental upset is highly colored by the personality traits. Some manifest confusion with depression, others manifest fears of injury by others, technically called paranoid projection, while others show excitement and restlessness. The mental mechanisms are mostly in the nature of conversion hysteria. The duration of the illness is dependent on the cause that gave rise to the psychotic upset.

The most striking and familiar examples of this type of reaction were the war neuroses or so-called shock cases. Most of the neurotic reactions observed during the war such as traumatic neuroses, neurasthenoid and various hysterical syndromes and convulsive attacks, were in the nature of conversion phenomena. I should like to say a few words regarding the conversion mechanism, for the reason that it is most interesting as well as to the point in this discussion.

By conversion, of course, is meant that somewhat obscure but very interesting psychologic mechanism by which the psychic conflicts of the individual are translated into physical symptoms. During the war, many cases of paralysis, blindness, aphonia and convulsive seizures developed that were of a purely functional character. That the underlying motive for such con-

version was the strong, unconscious wish to escape intolerable situations, such as fear, privations and hardships, is quite evident from the fact that as soon as these elements of hazard were removed, when the patient was invalided home or the armistice was declared, the great majority of these physical syndromes promptly disappeared.

It is important to call special attention in this connection to the fact that this very phenomenon of the conversion mechanism is continuously at work among the civilian population. During a war, obviously, the etiologic factors or unconscious motivations are quite sudden and overwhelming, whereas, during peace they naturally are of an insidious and gradual character, with resultant symptoms that are less potent and spectacular.

It is interesting to note that, since the criminal law has been reenforced making fourth offenders amenable to life imprisonment, there have been more frequent instances of the reactive type of disorder with conversion symptoms among prisoners. This reaction of conversion phenomenon developed in quite the same manner and with an almost similar kind of symptomatology as in the soldiers during a war, since the unconscious motivation for escape is just as overwhelming and compelling.

It is scarcely necessary to point out that many victims of conversion hysteria make the rounds from specialist to specialist, and most of the so-called cases of neurosis of the heart, gastro-intestinal disorders, headaches, insomnia, fainting attacks, dizziness, general weakness of various parts of the body, as well as vague complaints of genito-urinary disorders and various skin diseases belong in this category.

It may be observed further that a similar conversion mechanism, namely, unconscious lying or cheating oneself, is constantly made use of in the ordinary routine of life to avoid difficult and unpleasant situations without of course assuming the dignity of any definite illness.

Just to mention another equally interesting phase of this conversion phenomenon which is the converse of this—there is the patient who, instead of converting the mental conflicts into physical or somatic disorders, resorts to a diametrically opposite process for relief. Every physician has seen many patients suffering from serious chronic disorders, such as tuberculosis or some other progressive and exhausting organic disease, who develop certain mental attitudes in the form of undue optimism, often unreasonable and childish, and make elaborate plans for the future that are obviously impossible of being carried out. In other words, this type of patient also makes use of a similar conversion mechanism, making an unconscious effort to deceive himself of the seriousness of his disease and infirmity by developing mental symptoms, whereas others convert their mental conflicts into physical symptoms.

Space will not permit the discussion of the traumatic and other neuroses, all of which have practically similar mechanisms and motivations. However, I wish to emphasize again the central thought which the discussion of these conditions implies, namely, that there is not so much difference between the so-called physical and mental as has been unduly stressed that physical diseases are bound up with mental reactions, and that mental conflicts and disorders may be translatable into physical symptoms.

SCHIZOPHRENIC GROUP

The second is the schizophrenic or dementia praecox group, which has a protean symptomatology. For the purpose of this discussion, it is sufficient to say that schizophrenia is a serious mental disorder with an obscure etiology and pathology, despite the many theories prevalent at the present time.

The present attitude in psychiatry is to regard this as a trend reaction in which the basic symptoms are delusional ideas of a fantastic and bizarre character that are quite at variance with ordinary life. The inner unconscious conflicts and shortcomings of the patient are projected to the outer world and it is blamed for fancied persecution and oppression. Associated with this, there is also a shallow inadequate emotional reaction that is quite characteristic of this malady.

A sudden and fully developed attack of schizophrenia is not difficult to recognize—at least, its psychopathologic character, therefore this entity does not come within the scope of the present discussion. I shall briefly refer, however, to a type of schizophrenia, commonly called the simple type, that develops in a most insidious, gradual and protracted way, and that in its early stages may challenge at times the diagnostic acumen of even the most experienced.

A typical example is that of an adolescent boy who has always adjusted himself fairly well, has caused no trouble to his parents and has been looked on as a model child, frequently inviting the envy of his relatives and neighbors. He gradually becomes shy and lonely, dreamy and imaginative, he shuns the opposite sex and avoids social contacts. A boy of this type may undergo changes of personality that are so gradual that even those who come into intimate contact with him fail to recognize them. There is a gradual indifference to things in general and slight carelessness in personal habits. He becomes indolent, sluggish and lackadaisical and is inclined to stay indoors, sitting about idly, or gazing about more or less aimlessly.

These symptoms are so slight that at first the parents look on them with an indulgent eye—since he never has been a source of trouble and anxiety like the other children—but, as these traits persist sooner or later the parents become alarmed. Finally the physician is consulted and after making a careful physical examination he finds the boy "quite sound." He so informs the family, usually adding that the boy needs discipline, as he is in good health but lazy.

This kind of history one hears almost daily. In justice to the physician it must be said, however, that the average patient of this kind appears quite normal on casual examination. The somewhat shifty eyes, the indifferent and immobile facial expression, cold, clammy, often cyanotic hands, the disinclination to talk, with hesitating responses to questions, all these, in the absence of any obvious trends and delusions, cannot readily be recognized as evidences of any abnormal mentality, unless one has mental pictures of many similar cases. The most essential reason, however, for the physician's failure to recognize such cases is, let me again repeat, because he is not psychiatric minded, he is accustomed to think in terms of the physical or, putting it in another way, his training (or rather his lack of training) was such that he does not think of looking for mental situations and explanations unless they obtrude themselves on him.

What was said with regard to the preceding group, as a guide to the recognition of these mild obscure con-

ditions, is quite applicable here as well, namely, that the account and history given by the family should be accorded great weight and importance. In mild cases these patients are capable, even more so than in cases of mild depression or excitement, of dissimulating in the presence of the physician and appearing quite normal, especially if one is looking only for somatic anomalies.

Alcohol also plays a part in this group similar to that in manic depressive psychosis. It is a matter of clinical experience that in many potential schizophrenic patients, alcohol has been resorted to by the individual as a method of sublimation in an attempt to prevent the latent disease from becoming manifest. In other cases it might appear to act as a precipitant in that the individual may suffer from the toxic effect of alcohol in the form of delirium or hallucinosis which will mark the starting point of the schizophrenic attack.

ORGANIC PSYCHOSES

Organic psychoses are mental disorders that are an expression of coarse organic disease of the central nervous system. There are various types of organic lesions and injuries to the central nervous system, such as senile atrophy, arteriosclerosis, trauma causing injuries and damages to the brain substance itself, neoplasm, abscess, hemorrhage, encephalitis and encephalopathia. The psychopathologic symptoms of these conditions vary somewhat, according to the nature, extent and location of the organic pathologic processes, but the fundamental symptoms common to all, which are known to psychiatry as the organic reaction syndrome, are practically the same. The basic mental symptoms in all organic diseases of the central nervous system are clear enough when the disease is well developed, but often the earliest symptoms are subtle emotional changes or alterations in personality.

Because of limited space I shall merely refer to one organic psychotic disorder, the early recognition of which is most important to the general practitioner, namely, dementia paralytica, commonly known as paresis.

I need scarcely say that this is a condition of meningo-encephalitis of syphilitic origin. When a case of dementia paralytica is fully developed, there is rarely any difficulty in recognizing the character of the disease, but in the incipient stage it is sometimes most baffling. This is particularly so because, with the exception of comparatively few cases in which so-called neurasthenic symptoms are exhibited, these patients are not conscious of any ill health and therefore do not appeal to a physician for assistance. On the contrary there is a false sense of well being, exhilaration and superficial efficiency that obscures the picture and misleads even the family and friends. Occasionally these patients in addition will resort to alcohol, which masks and further complicates the clinical picture. The history and accounts of the immediate family and friends likewise are very often conflicting and contradictory.

The most important guide for the diagnosis under these circumstances is the occurrence of a gradual but radical change in the personality of the individual. If a man between the ages of 35 and 45, who heretofore has been well behaved, well mannered and temperate, a good father and a prudent business man, suddenly exhibits a marked change in his business, social and ethical principles, such a change should strongly suggest a possible case of dementia paralytica.

Of course, after the patient is in the hands of a physician, the earliest reliable symptoms are the changes in the pupillary action, lapses of retentive memory, irascibility and, above all, the characteristic disorder of speech that is almost pathognomonic of this malady. The unfortunate errors, however, in the early diagnosis of dementia paralytica happily have, during recent years, been reduced materially, owing principally to the fact that the serology is a great help in the diagnosis of these cases and that the average physician now most properly, as a matter of routine, makes serologic examinations.

I have briefly mentioned dementia paralytica for the sole reason that unless the condition is recognized promptly these patients are capable of doing much harm to themselves and particularly to their families, from a physical, social and financial standpoint. I have repeatedly seen the good name of a family as well as a respectable fortune blasted within a short period of time, solely because a patient was not brought under timely control.

THE TOXIC INFECTIVE AND EXHAUSTIVE GROUP

The fourth group, the psychoses symptomatic of somatic diseases, is still more familiar than the preceding organic type. These mental disturbances are obviously the expression of various toxic and infectious disorders, as well as of the profound exhaustion due to chronic and debilitating physical diseases. The mental symptoms are essentially similar to those of the coarse organic brain diseases, with the exception that the symptoms of the former are more acute and pronounced than those in the organic psychoses.

The action of all toxemias caused by exogenous and endogenous poisons, as well as profound debility and exhaustion, on cortical cells is in the nature of a trauma, hence the similarity of the psychotic symptoms. The perceptive faculties are seriously affected, giving rise to false sense perceptions—clouding of consciousness, disorientation and a dreamy and confused mental state, otherwise known as delirium, with which the general physician is so familiar, since these conditions are encountered mostly in private medical practice and in general hospitals. The type and intensity of the delirium are determined by the variety and degree of the poison, as well as the personality make up and susceptibility of the individual patient. Among such conditions may be mentioned alcohol and various other exogenous poisons, also endogenous poisons due to uremia, diabetes, anemia, cardiac disorders, tuberculosis, hyperthyroidism and many other conditions that are too well known to need mention.

The diagnostic difficulties in this group are much less than in other types of psychotic disorders. Unlike other mental disorders, there are physical illnesses that stand in a causal relationship to the mental disorder and make the recognition of this type of psychosis much simpler.

The detailed discussion of the treatment and handling of these conditions in general practice, from a psychiatric point of view, although interesting and profitable, will not be entered into here.

The treatment in these cases depends obviously on the underlying physical condition. One should be very conservative in the liberal and especially the persistent administration of hypnotics and sedatives of various sorts, as obviously these are apt to intensify the mental condition or produce it in susceptible patients. However, when given only at times of absolute necessity,

they should be given in sufficiently large doses to bring about the desired rest and sleep, but should not be continued for long periods. Psychotic patients of all kinds have an astounding tolerance for hypnotics and sedatives, and if they are given in repeated small doses restlessness is apt to be aggravated. If this is interpreted as an indication for larger and larger dosage, a drug delirium may be superimposed on the primary disorder.

Another important factor is the environment. Keeping in mind the nature of the mental symptoms, particularly the disorders of perception, various hallucinations and mental confusion, one should provide a very simple environment, with abundant light and air, with as few persons in attendance as possible, otherwise fatigue and disquieting distractions will accentuate the mental symptoms. It should also be added, however, that the attending physician at times seems to become unduly alarmed as soon as mental symptoms appear and shows a tendency to transfer the patient immediately to a hospital.

While it is true that some of these patients eventually need to be taken to a psychiatric hospital, many of them may, if properly treated, have an illness of short duration and can with marked success be treated at home or in a private room in a general hospital, provided of course, that the facilities will permit. Transferring a patient suffering from this type of symptoms to strange surroundings, particularly to crowded and more or less turbulent hospital wards, with their panoramic and complicated activities, frequently intensifies the delirium and mental confusion.

I am conscious of the fact that I have given a rather sketchy discussion of the psychiatric problems which may arise in general practice, and of necessity have not touched on many important problems. Furthermore, the foregoing facts, rapidly reviewed, have been presented mainly from the standpoint of a background for the brief discussion of psychotherapy which, I believe, is the psychiatric problem of far-reaching importance in general medicine.

PSYCHOTHERAPY

What is psychotherapy? It is the art of making use of the mental attitude of the patient as a curative factor in the treatment of his illness. Psychotherapy is directly dependent on the faith or the confidence of the patient that his illness will be cured. It matters little, as far as the patient is concerned, whether this faith or confidence is inculcated in him through a person or group of persons, or whether it is an agency which is tangible or a mere fancy. Every one readily admits the great potency of faith and confidence in all walks of life, the will to do, optimism, self reliance and self confidence are admittedly the essential qualities and factors for success in life. I have always thought that man makes use of only a very small fraction of the talents with which Nature has endowed him.

I have occasionally seen a patient who, despite his diseased and disordered mentality, has accomplished things that he was absolutely incapable of doing prior to his illness, this was possible because the critique, as a result of the mental disorder, was in abeyance and the patient could therefore give full sway to his native endowments.

But when it comes to the medical profession—the healing art—one is not inclined to accord a great deal of value or virtue to “purely” psychologic factors. Almost daily one hears of religious or semireligious

organizations that have established new clinics for the treatment of the sick. The number of healing cults of various kinds is legion—even the fortune tellers, clairvoyants and astrologers derive the greatest part of their income from invalids. One is accustomed to look on these reports with ridicule and ironic skepticism, assuming them to be false and chicanery, and often justly so. But is it reasonable to think that these cults of various kinds could multiply and prosper if they did not, at least to some extent, deliver some sort of wish-fulfilling relief? While they undoubtedly do a tremendous amount of harm and irreparable injury to many, the real fact is, and investigation will confirm it, that even the very garbled, distorted use or misuse of the principles of psychotherapy, no matter under what cloak, accomplishes much, healing some, ameliorating others and comforting all.

In a recent life of Pere Marquette, known as the apostle to American Indians, the following significant observations appear:

Among certain tribes the medicine men believed, or professed to believe, in suppressed desires as the cause of disease. They believed that there are two main sources of disease, one of these is the mind of the patient himself, which unwittingly craves something and will torment the body of the sick man until he possesses it, for they hold that there are in every man certain inborn desires, often unknown to himself, upon which his happiness depends. For the purpose of ascertaining such innate and ungratified appetites, they summon soothsayers who they think have a supernaturally imparted power to look into the inmost recesses of the mind.

Is this not an astonishingly accurate outline of the principles of dynamic psychology? One might almost suspect that this hypothesis and belief on the part of this primitive people was formulated by the followers of Freud.

The priests and doctors in ancient times, or the medicine men among primitive peoples, were the prototypes of various healing cults. Obviously in the absence of any scientific knowledge of the human body and its functions, they discovered certain principles of psychotherapy empirically, as a curative force, and tinctured them with magic, superstition and mysticism, in the manner followed by the modern cults.

Furthermore, psychotherapy as a healing force is evidently much more ancient than the practice of medicine based on physiologic principles alone. Is it not possible that scientific medicine, in its endeavor to shake off superstition and black magic has swung to an opposite extreme and has discarded psychic factors entirely, thus becoming perhaps too materialistic?

As has been pointed out psychotherapy presupposes a sentient and selective relationship toward the source of the healing force, namely, the physician. I should like briefly to refer here, even at the risk of digression, to the fact that this very psychologic principle, namely, that the patient must have freedom of choice in the selection of his physician, is the most serious objection to the socialization of medicine. The experience of large organizations, civic, industrial, military and otherwise, that provide medical care for their members, has amply demonstrated this fact. Such organizations although, as a rule, very well equipped, have failed to render satisfactory medical care commensurate with their effort and investment. The directors of the medical services of municipal police, fire and sanitation departments and many similar organizations readily admit that the sick members of such groups always prefer to be treated by physicians outside of the organi-

zations. In other words, they would rather be treated by physicians of their own selection. During the late war, although the army had well organized medical units in the various military camps, there was a definite tendency on the part of the soldiers to seek medical aid from physicians in the neighboring villages and towns.

I think one is justified in asserting that socialized medicine would endanger public health by depriving the individual of one of the basic and most effective factors of therapy.

The use of psychotherapy in psychiatry has made tremendous progress in the past two decades and has acquired a fairly well defined and scientific technic. Just to mention some of these methods:

First. Simple advice and counsel, well directed, with full knowledge of the situation regarding the patient's problems and difficulties.

Second. The method of persuasion which consists of the elaboration of the former, with a more logical, forceful and convincing discourse, going into considerable detail in a constructive manner as to the significance of the conflicts and how to meet the situations.

These two are simple, common sense methods that are made use of by every one and that are applicable to everyday affairs of life.

But the more effective methods of psychotherapy are those by which one can obtain important information concerning the patient's personality make-up and his intimate problems and conflicts, not only of the present but of the remote past as well. A substantial and enduring readjustment by means of psychotherapy can be brought about only through a clear recognition of such conflicts. Frequently the patient himself is not conscious of them. Among the more effective methods of psychotherapy may be mentioned:

1. Hypnotic catharsis. This technic consists in making a searching inquiry into the life history of the patient while he is in a state of hypnosis, with a view of uncovering his conflicts, longings and disappointments. The patient is encouraged to talk spontaneously and without interruption, except for occasional questions to direct the trend of associations. Many physicians are familiar with Dr. Breuer's famous case of a young neurotic woman who was successfully treated by this method. Breuer later directed the attention of Freud to the case, and it was their joint investigation which may be said to have marked the cornerstone of psychoanalytic psychology.

It should be said in passing that hypnosis as a therapeutic measure has again been revived in recent years, particularly abroad, after having fallen into disuse for several decades.

2. The most important and valuable method of psychotherapy is the psychoanalytic method, for which a definite technic has been developed, based on the principles of free association.

The fundamental principle in the psychoanalytic method is to uncover the individual's childhood and infantile experiences, which Freudian psychology assumes to be the cause of later neurotic conflicts. It is believed that in this manner the neurotic patient will again, as it were, live and re-experience these infantile psychic traumas, with the result that their painful emotional value will disappear by being brought into consciousness.

The psychoanalytic psychology has been more or less modified from time to time by various former pupils of Freud, notably Jung and Adler, who have established

separate schools of psychoanalytic psychology with some following. Such modifications, however, refer only to the Freudian psychology, but not to his psychoanalytic method or procedure, which still remains a monument to his genius.

3. The reeducation method. This is made use of, as the term implies, as an aid in all psychotherapeutic methods, supplementing them and utilizing the important information obtained in the upbuilding of the patient's personality. The reeducation method is especially effective if combined with hypnotic suggestions.

It is, of course, quite clear that in the various methods of psychotherapy, the fundamental effort is to secure the confidence of the patient or, speaking psychoanalytically, to establish transference on the physician. Secondly, and equally important, is a clear understanding on the part of the physician of the conflicts of the patient in order that psychotherapy may be applied in a systematic and well directed manner. The method and technic of psychotherapy are modified according to various circumstances, such as time, character of the illness and reactions of the patient.

The question may properly be asked whether psychotherapy has any place at all in general medicine (since the latter deals mostly with somatic disorders) and if so to what extent? Some years ago such a question would have evoked incredulous skepticism, but now, happily such is not the case. The value of psychic factors in the treatment of somatic diseases is fully appreciated by almost every physician. The problem now is rather its technic and its practicability in the course of a crowded general practice.

As has already been stressed, the physician's ideas of physical and mental conditions have undergone radical changes; he now knows that the difference is not so great, that all mental diseases, whether functional or organic, have a somatic component and that all somatic disorders, however slight or insignificant, have mental reactions. It is no longer speculative to state that the mental attitude of a person, including his emotional reaction, is capable of acting directly on the bodily functions or even on the tissues in such a manner as to cause pathologic changes, or at least to contribute to the development of disease processes. The physician no longer thinks in terms of the "purely" mental and physical, but rather how much of the mental and how much of the physical; he recognizes that psyche and soma are one and inseparable. It is also quite clear and certain that every person suffering from physical disease develops a definite mental reaction toward such a disease, and that the emotional and mental attitude in turn is capable of either enhancing or retarding the curative processes. It is at least to this limited extent that the general practitioner is able to and should practice psychotherapy.

Incidentally this revolutionary change in the general conception of the physical and mental has given great impetus to restoring psychiatry to medicine and medicine to psychiatry. There is at present a definite movement on foot throughout the country, especially in hospitals, to integrate the medical, surgical and psychiatric points of view under the same roof. The new psychiatric unit of Bellevue Hospital was conceived, planned and organized with this very purpose in mind, namely, to afford every facility for the combined effort of the surgeon, physician and psychiatrist in the treatment of the sick, and I think it is one of the earliest as well as the most comprehensive endeavors of its kind.

I fear that in speaking of psychotherapy and its technic as applied to psychiatry I may have conveyed the impression that the practice of psychotherapy in general is a formidable and complicated procedure. But such is not necessarily the case. Psychotherapeutic principles are quite simple and constitute the chief factors in all human relationships and activities—social, religious, political and commercial. The skilful salesman and the astute politician owe their success to psychologic principles similar to those which enable the physician to gain the confidence of his patient. The nature of the physician's professional work—the practice of medicine—is peculiarly adapted to the promotion of psychotherapeutic principles. He comes into contact with various types of personalities, young and old, rich and poor, good and bad, saint and sinner, divested of false pretense and veneer, and in the true nakedness of their character, thus he has the opportunity to gather accurate knowledge and experience as to types, traits and reactions which are so essential and indispensable in the practice of psychotherapeutics. In fact, whether he wills it or not, the physician is a psychotherapist and practices it daily in his professional work. He is forced to do so by his patients, since they look for it and demand it. Most physicians practice it unconsciously and some, although appreciating its value in a general way, carry it on in a haphazard, desultory manner.

My plea is to be conscious of this psychotherapeutic power and to practice it in a systematic and well directed manner. If I were asked to suggest a simple formula for the utilization of psychotherapeutic principles in general medicine, I should say: Be psychiatric minded, first, last and all the time. While making repeated routine examinations of the pulse, temperature and various organs and functions of the body, do not ignore the mental, surely not an inconsiderable function. Why not add to one's general routine the habit of evaluating each patient's personality and mental makeup, his general emotional reaction, his appearance and demeanor while under examination, noting particularly his emotional reaction toward his complaint and illness.

Let the patient talk not only about his illness but also about himself and his personal affairs and relationships freely and spontaneously, and with as little interruption as possible. Let him tell his story in his own way. With a procedure even as simple as this, it is amazing the amount of information that the patient will disclose, revealing valuable psychic and emotional factors intimately related to his physical illness or complaints.

It should be remembered that in the application of psychotherapy, consistency is of the utmost importance. The value of reassurance, confidence, hopefulness and well directed advice in the treatment of the sick is readily admitted, but it is frequently overlooked that in order to be effective, psychotherapeutic principles must be utilized, not only in words, but in deeds as well, not in a haphazard and aimless manner, but by following a deliberate and well laid plan with a definite goal. To reiterate, there should be in psychotherapy continuity and intelligent consistency, just as obtains in physical therapy.

With a fully developed consciousness and a modicum of technic, psychotherapy yields results far beyond one's expectations.

If the interest and enthusiasm of the younger generation of physicians in psychiatry, and particularly that of the undergraduate students, may at all be regarded as a criterion, it may safely be predicted that the time is not far distant when the physician will not be content to be

merely a skilful physical diagnostician and therapist but will be a doctor of the mind as well, and when to his skill and intelligence he adds these human qualities of clear and comprehensive insight into the psychic conflicts of his patient, he then becomes in a glorified way the doctor and priest of old, but with science and humanity as his aids, instead of superstition and reliance on the magical and the miraculous.

CONCURRENT OSTEOGENIC SARCOMA IN BROTHER AND SISTERS

C. W. ROBERTS, M.D.

Associate in Surgery, Emory University School of Medicine

AND

CHARLES PURCELL ROBERTS, M.D.

ATLANTA, GA.

Instances of the development of sarcoma in successive generations have been reported.¹ The appearance of simultaneous, symmetrical sarcoma in uniovular twins has been described by McFarland and Meade,² but we

Fig. 1.—Left to right: Matilda T., aged 17 years; Lennie T., aged 13 years; and George T., aged 23. Note enlargement in lower right thigh of Matilda T.

have been unable to find a previous report in medical records of the spontaneous and concurrent development of bone sarcoma in several members of one family, a brother and two sisters, aged severally 23, 17 and 13 (fig. 1).

These cases are presented therefore, with the hope that they may complement the evidence in favor of

¹ Silcock, A. Q. Hereditary Sarcoma of Eyeball of Three Generations. *Brit. M. J.* 1: 1079, 1892. Pinard, M. and Versini. Case of Probable Hereditary Transmission of Sarcoma. *Bull. et mem. Soc. med. d. hop. de Paris* 62: 653-657 (May 3) 1928.
² McFarland, J. and Meade, T. S. Genetic Origin of Tumors Supported by Simultaneous and Symmetrical Occurrence in Homologous Twins. *Am. J. M. Sc.* 184: 66-80 (July) 1932.

some of the disputed assumptions concerning the etiology of sarcoma and may possibly suggest leads in the study of the disease

CASE 1—History—George T., aged 23, a farm boy, complained of pain and swelling about the right knee. In August 1933 he began to suffer slight "rheumatic" pain and stiffness

Fig 2 (case 1)—Right knee showing sclerosing type of osteogenic sarcoma

of the right knee. He believed that this was due to walking on concrete pavement, so he quit the job which involved this and stayed on the farm. Some improvement followed, and he was able to work until December 30 when he received a severe blow on the right knee, a large limb on a felled tree, bent and under great tension,

flew against his knee when it was suddenly released as he chopped it. He suffered considerable pain at the time and became faint. He was unable to walk for several days owing to the swelling about the joint. The condition improved for a time but he began to notice a localized mass about the antero-medial aspect of the upper extremity of the tibia the latter part of January 1934 the knee becoming swollen, painful and limited in its motion. About three weeks later the tumor was lanced but

Fig 3 (case 1)—Thorax showing metastasis to the lungs

neither fluid nor pus was obtained. The mass about the knee steadily and gradually increased in size the distal leg and foot becoming edematous. The patient continued to have much pain about the knee. He had lost 40 pounds (18 Kg) in three months and was brought to the Georgia Baptist Hospital, March 19.

The patient had had pneumonia in 1929 otherwise his past history was without significance.

The family history is common to the three cases reported in this paper. There have been no other neoplasms in the family so far as is known. The people are of Irish English extraction. The paternal grandparents were second cousins and died of cardiovascular disease at 60 and 65 years. There were several cases of tuberculosis in the mother's family. She and the father were in good health. The Wassermann and Kahn tests were negative for both. The paternal aunts have large families in good health with no history of tumors. Besides Matilda, aged 17, and Lenmie, aged 13 (see individual histories), there are three other sisters, aged 21, 19 and 10 years, and a little brother, aged 6 years, all in good health.

Several years before the father had a slow growing tumor on the calf of the leg. It opened spontaneously and drained a mealy substance. Healing ensued and now on examination the site of the tumor presents a normal scar.

Examination—Physical examination March 21 showed notable emaciation. The temperature was 98.3 F, the pulse 80 and the respiration rate 22. Only the right knee and leg were of interest. The leg was maintained in an attitude of flexion. Anteromedial and just distal to the right patella there was a firm, fixed mass the size of a large orange. Centrally the mass was fungating and soft, the site of the lancing unhealed.

Fig 4 (case 1)—Section from tumor showing spindle cells and syncytial giant cells. The stroma is more conspicuous than in sections from the other two cases. Osteogenic sarcoma

Movements of the knee were painful and limited. The leg and foot showed pitting edema.

The blood Wassermann and Kahn tests were negative. The red blood cells numbered 4,220,000 (dehydration), with hemoglobin 85 per cent, white blood cells, 11,900, neutrophils 92 per cent, large lymphocytes 2 per cent, small lymphocytes 6 per cent.

The urine was scanty with much phosphate sediment and a total acidity of 75 degrees.

Roentgen examination of the right knee (fig 2) showed a large dense mass about the head of the tibia. There was a trabeculated bone deposit extending out into the mass. The upper third of the tibia presented a marked increase in density, especially in the posterior cortex. There were some areas of bone destruction in the shaft.

There was a large nodule in the outer zone of the upper margin of the lower left lobe (fig 3). The nodule measured about 5 cm in diameter and lay in the fourth interspace in the axillary line. A small nodule was to be seen just below the large one. There was a small nodule in the lower right lobe directly behind the anterior end of the sixth rib.

The diagnosis was sarcoma of the right tibia of the sclerosing type with metastasis to the lungs.

Progress Notes—The patient continued on to a cachectic state. The tumor became quite large (the size of a small

watermelon) and the leg and foot enormously swollen. When seen a few days before the patient's death, May 19, the tumor was dusky and extremely vascular.

Microscopic Study—The tumor was highly cellular and malignant. Many medium-sized giant cells were present (fig 4). The final diagnosis was round-cell osteogenic sarcoma.

CASE 2—History—Lennie T., a schoolgirl, aged 13 years, complained of a painful mass about the right shoulder. When coming home from school about the middle of January 1934, the patient tripped and fell on the sand road striking the right shoulder. She suffered immediate pain in the shoulder and noticed interference with motion. The physician manipulated the arm in an attempt to reduce what was thought to be a dislocation but desisted after complaint of extreme pain. She was in bed three weeks, crying often, owing to the very painful shoulder, which was somewhat swollen. After she got up the shoulder looked much better for a few days, then it began to swell again. Gradually a mass appeared about the antero-medial aspect of the right shoulder. She continued to have much pain and lameness of the right shoulder.

Her past history revealed nothing of importance other than a fracture of the right clavicle three or four years previously.

Examination—March 19, 1934 the temperature was 99.2 F, the pulse 100 and the respiration rate 22. The patient was fairly well nourished. The shoulder alone was noteworthy. There was a hard, immovable tumor attached to the antero-medial aspect of the upper third of the right humerus. There was slight warmth and redness but no bruit. The mass was of infiltrative hardness. There was some limitation of the movements of the shoulder joint.

The blood Wassermann and Kahn tests were negative. Examination of the blood showed red blood cells, 3,330,000, hemoglobin, 75 per cent, a slight increase in thrombocytes, white blood cells, 6,800, neutrophils 86 per cent, large lymphocytes 1 per cent, and small lymphocytes, 13 per cent.

Examination of the urine showed sugar negative, albumin, 2 plus, total acidity, 10 degrees, no casts, from 6 to 8 erythrocytes and from 10 to 12 pus cells to a high power field.

Roentgen examination, March 30, of the right shoulder (fig 5) showed complete destruction of the upper third of the right humerus. A pathologic fracture was seen in the upper third of the bone. A large mass about the osteolytic area infiltrated the soft structures. There was considerable bone deposit in the mass. Extension of infiltration was only to the epiphysis above, not involving the humeral head.

Fig 5 (case 2)—Right shoulder. Osteogenic sarcoma bone destruction medial to tumor. Note elevated periosteum. Clavicle shows healed fracture at junction of middle and outer third.

The diagnosis was destructive osteogenic sarcoma.

The chest showed no metastasis on roentgenograms made in the middle of March and later in the middle of May.

Radiotherapy was administered March 24 and again three days later. There was no response.

Progress Notes—As the tumor enlarged the patient became more and more anemic and finally cachectic repeating her brother's course. She died July 7.

Microscopic Study—Section (fig 6) shows highly cellular tissue. The cells were round and embryonal in type. The final diagnosis was round-cell osteogenic sarcoma.

CASE 3—History—Matilda T., aged 17 years, complained of intermittent, subacute pain in the lower third of the right thigh. About the middle of February 1934 she began to notice an occasional pain. The pain was not brought on by activity. There was no radiation of the pain and no regularity of occur-

Fig 6 (case 2)—Section from tumor showing irregularity in size and shape of cells together with syncytial giant cells. Stroma is scanty. Numerous mitotic figures. Osteogenic sarcoma.

rence. Toward the last of March a bulging became apparent. This gradually increased in size, and she continued to have pain. There was no disability of the right lower extremity. There was no history of trauma.

Examination—May 20 the temperature was 96.3 F, the pulse 100 and the respiration rate 20. The patient was well developed and fairly well nourished in appearance. Only the right thigh was of interest. There was an early spindle-like enlargement of the anteromedial aspect of the thigh at the junction of the middle and lower thirds, visible on inspection. The mass was not sensitive on manipulation. Movements at the knee joint were not reduced in range. The mass was felt to be of indurative hardness and could be palpated on the anteromedial surface of the lower third of the right femur, encircling the bone throughout half of its circumference. It was not movable but firmly attached to the bone. The crural nodes were not palpable.

The blood Wassermann and Kahn tests were negative. Chemical analysis of the blood showed red blood cells 3,920,000, hemoglobin 65 per cent, white blood cells, 9,400, neutrophils, 74 per cent, lymphocytes, 26 per cent, a slight increase in thrombocytes, blood typing Moss II. Analysis of the urine showed 2 or 3 erythrocytes and 2 or 3 pus cells to a high power field.

Roentgen examination of the right thigh, April 14, revealed an area of osteonecrosis involving about 7.5 cm of the lower third of the right femur (fig 7). Greater destruction was noted along the anterior cortex than posteriorly, with some elevation of the overlying periosteum. There was a mass in the soft structures about the area of bone destruction, lying beneath the muscles.

Examination of the chest revealed no metastatic nodules.

The diagnosis was probable osteogenic sarcoma, but the condition had the appearance of syphilitic osteomyelitis.

Microscopic examination of a piece of tissue, April 25, revealed that it was largely fibrous and contained many fibroblasts. There were only a few blood vessels. There was considerable leukocytic infiltration.

The impression was that there was inflammatory change and that the growth was nonmalignant.

Because of these reports, amputation was delayed for about one month. Operation was not scheduled until serial roentgenograms had offered further support of the probability of a malignant condition.

May 5 there was an extension of bone destruction longitudinally in the shaft and no new bone production.

May 15 there was no involvement of the long bones or chest.

Fig 7 (case 3)—Anteroposterior and lateral views of the lower right femur showing bone necrosis and encircling soft tissue tumor beneath the muscles.

May 18 progressive destruction was present along the shaft of the femur and no bone regeneration. The dense tumor still was confined beneath the muscles surrounding the area of osteonecrosis. It appeared to arise from the outer layer of the periosteum (fig 8).

Amputation was carried out, May 23. It was decided not to attempt enucleation at the hip joint because of the girl's general physical state. A high upper third amputation of the thigh was done. The patient's condition toward the end of the operation was unsatisfactory, subcutaneous epinephrine and intravenous saline solution being administered to combat circulatory collapse. A blood transfusion was given after the amputation.

Pathologic examination of the lower two thirds of the right femur revealed that 9 cm above the condyles there was a firm spindle-shaped tumor mass lying in direct proximity to the bone shaft and completely surrounding it. The mass measured 9 by 2.5 cm. There was a necrotic cavity in the shaft of the bone, 4 cm in length and directly beneath the tumor. The bone marrow was soft and necrotic for a distance of 4 cm below and above the cavity. The latter was filled with dark bloody fluid and soft necrotic material.

On microscopic examination the extracortical tumor was reported fibrosarcoma with a rather low grade of malignancy. Figure 9 is a section from the medullary portion of the tumor.

Progress Notes—The postoperative course was uneventful after a rather persistent tachycardia for a time. On gradually regaining strength she was able to leave the hospital and return home. When seen two months later she was in very good health, had maintained her average weight and was without discoverable metastasis.

Two months later, however, the patient reported for examination, complaining of persistent chest pain, a harassing brassy cough and weight loss, and on roentgen examination multiple metastatic nodules were found widely distributed in the lung fields. The patient died Jan 29 1935.

COMMENT

1 These cases strongly support the hypothesis of a genetic origin or diathesis in the development of malignant tumors.² It would appear that a spontaneous susceptibility to autonomous cell growth was resident in the osseous systems of these individuals and perhaps localized to it. Further, it is to be noted that three different major long bones were the sites of origin of the tumors. The appearance of all three sarcomas in a right extremity is perhaps fortuitous, rather than dependent on dextralateral segregation of the "malignant factor" during ovid division.

2 The contemporary occurrence of the tumors, moreover, suggests the presence of some adjuvant extraneous factor or factors.

Trauma—Taken as a group, these cases indicate that injury was never the primary exciting cause but that its role was definitely one of aggravation and acceleration of already existent sarcoma. In case 3 there is no history of trauma. In each of the other cases it is to be noted that there was a rapidly appearing tumor at the site of injury. But it must be borne in mind that patient 1 had complained of pain for four months prior to the blow he suffered—pain of such consequence as to make him quit his job—and that patient 2, although asserting that there were no symptoms of any character before her accident, seems definitely to have sustained a pathologic fracture, indicating the silent growth of

Fig 8 (case 3)—Lower right femur four weeks later than in figure 7 showing marked extension of bone necrosis both in cortex and in medulla of the femur and increase in size of surrounding tumor.

intramedullary sarcoma (fig 5). Our belief that the fracture did not primarily excite malignant change is strengthened by the fact that patient 2 had broken her right clavicle three or four years earlier, when she had fallen down a cliff, and normal healing had resulted (fig 5). In this connection it is of interest to note that in April 1934, while his brother and sisters were suffering from sarcoma, William T. Jr., aged 6 years, sustained a fracture of the left clavicle. Follow up

roentgen examination showed normal callus formation, with no other abnormalities involving the bones of the shoulder. Healing was rapid and to date has been uncomplicated.

(These cases are not to be confused with those in the multiple fracture family reported by Werner.³ There is nothing here to indicate chronic bone disease as a ground for the superimposition of sarcoma.)

In case 3, of course the degree of influence of surgical insult at biopsy cannot be estimated, but radiologic study (figs 7 and 8) showed rapid extension of bone destruction subsequent to the diagnostic operation.

Infection—Unless the concomitance of the three cases can be assigned to chance, the instance offers the possibility of a specific infectious agent in the outset. The constitutional symptoms were not, however, suggestive of an infectious process. Culture and smears of bone marrow at the time of amputation in case 3 revealed no organisms.

Fig 9 (case 3)—Section from tumor showing round cells fairly uniform in size with rather pyknotic nuclei. The stroma is scanty. Osteogenic sarcoma.

Bone Growth—Kolodny's⁴ conclusion from statistics of the Registry of Bone Sarcoma that energetic bone growth, with its underlying endocrine influence, is a signal factor in the etiology of osteogenic sarcoma can well be applied here and must be considered in analysis.

Dietary—That there may be some dietary deficiency factor bearing a primary or aggravating role in the development of sarcoma is suggested by the environment in which this family lived. The nine persons living in a bare, three-room shack, were receiving meager support through federal relief. Although grossly they appeared to be well nourished it is plausible to assume that their economic status failed to provide a balanced fare.

OCCLUSION OF THE POSTERIOR INFERIOR CEREBELLAR ARTERY IN CARDIOVASCULAR DISEASE

SIEGFRIED BAUMOEL, MD

AND

M D FRIEDMAN, MD

CLEVELAND

Cerebral vascular accidents may occur in any part of the brain, but it is common knowledge that the great majority of such accidents involve either the motor cortex or the internal capsule and produce here the classic picture in which the obvious hemiplegia plays the most prominent part. The two conceptions "stroke" and hemiplegia are therefore closely associated in the minds of most medical men. There are, of course, apoplexies in other localities of the brain, apoplexies without hemiplegia but with otherwise characteristic symptom complexes. It is our purpose in this communication to point out such a locality in the brain where vascular accidents occur much more frequently than is generally believed. We shall further point out that they can be readily recognized if one becomes familiar with their symptomatology and that their recognition is of far more than academic interest because of important clinical and prognostic peculiarities that they entail. The locality to which we refer is the lateral portion of the medulla, and the pathologic lesion in these cases is occlusion of the posterior inferior cerebellar artery.

A brief review of the anatomy and the circulation of the medulla with a consideration of the structures involved, will aid greatly in understanding the clinical picture.

The medulla is supplied by branches from the vertebral anterior spinal, basilar and posterior inferior cerebellar arteries. These vessels send paramedian branches which irrigate the pyramids and midline structures. They send also long and short circumferential branches into the substance of the medulla. A branch of the posterior inferior cerebellar artery supplies that sector which extends roughly from the outer border of the olive to the restiform body. It is an interference with the functions of the structures lying in this sector that gives the signs and symptoms of the lateral medullary syndrome. Thus one has

- 1 Involvement of the fibers from the vestibular nucleus resulting in dizziness, nystagmus, falling reactions and the like. The cochlear portion is for anatomic reasons rarely involved, but if it is affected one gets only partial deafness and tinnitus.

- 2 The restiform body which may be affected causing some hemiparesis.

- 3 Involvement of the ninth nerve, giving disturbance of sensation in the pharynx and soft palate and disturbance of taste in the posterior third of the tongue.

- 4 Involvement of the tenth nerve, causing (a) disturbance of movement of the soft palate and interference with the function of the pharyngeal constrictors and (b) paralysis of the vocal cord on the side of the lesion.

- 5 Involvement of the nucleus and descending root of the fifth nerve. This results in a hypesthesia of the face, cornea and mucous membrane of the nose on the homolateral side.

- 6 The spinothalamic tract, which is practically always caught and produces a contralateral hypalgesia, perhaps the most constant feature of the syndrome.

- 7 In a certain percentage of cases the catching of the oculo pupillary fibers as they pass through this region of the medulla producing a Horner's syndrome on the side of the lesion.

It is only fair to mention that the French writers, especially Forl and his associates differ somewhat from this view, as they divide the medullary syndrome into an upper and a lower one. They state that the upper syndrome is due to an occlusion of the arteria fossae lateralis bulbi, a branch of the basilar artery, and that the lower syndrome alone is due to an occlusion of the posterior inferior cerebellar artery, another branch of the basilar artery. Most references in the literature, however, disagree with the French view and still hold to the older conception which was first propounded by Wallenberg¹ and which represents the view most widely accepted today.

CLINICAL PICTURE

In unfolding a clinical picture produced by occlusion of the posterior inferior cerebellar artery, it must be emphasized right at the outset that, in contradistinction to the classic apoplexy, the attack is practically never ushered in with unconsciousness. In none of our cases did unconsciousness occur during the attack. The patient avers that something has happened to him and he may feel quite distressed. Yet the examiner is often not much impressed by the vague complaints and may attribute these to the underlying ailment or to a neurotic disturbance so frequently superimposed on organic disease. Such a fateful mistake is easily explained by the fact that one-sided lesions of the medullary structures involved cause so few and such equivocal disturbances in function that only a most minute examination will detect them. It is common knowledge that a one-sided paresis of the soft palate, the pharynx or the larynx produces very little disturbance to the patient. The larynx, unfortunately, is rarely examined by the internist or neurologist unless a definite complaint is registered by the patient and nystagmus is for some reason or other, not given the consideration that it deserves.

Fig 1—Diagrammatic sketch of the medulla modified from Wilson demonstrating the area in the lateral corner of the medulla that is involved by occlusion of the posterior inferior cerebellar artery. A vestibular nucleus B restiform body C nucleus of the ninth nerve D descending root of the fifth nerve E motor nucleus of the tenth nerve F spinothalamic tract

In other cases, again, the onset of the attack is more stormy or the emotional make-up of the patient less susceptible to neurotic disorders, and then the physician is strongly impressed by the organic nature of what has happened to the patient. The actual sequence of events in the vascular accidents under discussion is as follows. A patient having been treated for a cardiovascular condition or in whom such a condition has been anamnestically established suddenly develops

Meniere's syndrome. His trouble is usually ushered in by a more or less severe dizziness accompanied by vomiting. These phenomena dominate the scene for a day or two. Then other symptoms gradually begin to make their appearance, such as difficulty in swallowing, some disturbance in articulation or perhaps some sensory disturbances. Again it is not these subjective symptoms but the objective signs always accompanying the former that will disclose the real situation.

The clinician who suspects the real significance of the Meniere episode will not have to wait for the appearance of these symptoms but will be able to observe from the beginning certain objective signs that will at once point the way to a correct diagnosis. Of these objective signs the most important one from a diagnostic point of view is the nystagmus. The nystagmus is so valuable a sign because it can be readily visualized, because it is beyond any doubt an objective sign and because it will lead one on to the right track of clinical interpretation and localization.

Fig 2 (case 2)—Gross appearance of the medulla with a magnification of 1/2 diameter showing the destruction in the lateral corner of the medulla.

Next in diagnostic importance is the paralysis of one vocal cord. This is almost always present, although, as mentioned before, it will rarely betray itself by any appreciable impairment of function. It must and should be looked for. It will at least in some cases, clinch the diagnosis and point to the exact site of the accident. The other signs, as enumerated in the anatomic introduction, may vary as to their number and intensity and help merely to confirm the diagnosis. Among the latter there is one very significant sign, particularly when the nystagmus and vocal cord paralysis are not so manifest. This is a crossed sensory disturbance involving the face on the side of the lesion and the rest of the body on the opposite side. The anatomic explanation for this phenomenon is found in the involvement of the nucleus and descending root of the fifth nerve, fibers of which have not yet crossed, and the spinothalamic tract, the component fibers of which have all crossed in the cord. This also explains the fact that the sensory involvement is limited to pain and temperature. As a rule, these sensory disturbances are not complete. They may be limited to a homolateral corneal anesthesia and to islands of partial anesthesia on the other side of the body. These disturbances, however, are not as obvious as the nystagmus or as striking as the vocal cord paralysis. They must be painstakingly searched for to be elicited.

All these signs and particularly the symptoms diminish gradually in their intensity, but some traces of them will persist indefinitely. It is one of the distinguishing features of this vascular accident as contrasted with the classic apoplexy that the prognosis is definitely more favorable. There are occasional exceptions with a fatal termination. These occur when the lesion is caused by hemorrhage that spreads beyond the bounds of this sector, causing more extensive medullary damage—always a most serious disorder.

DIFFERENTIAL DIAGNOSIS

A differential diagnosis will only rarely come in question, but there are other lesions which can affect this region and may occasionally simulate its vascular etiol

ogy Thus multiple sclerosis may begin in this region and cause confusion in diagnosis With multiple sclerosis, however, other signs referable chiefly to the pyramidal tract or other characteristic regions will soon manifest themselves Of course the acuteness of the onset is not so striking in multiple sclerosis

Secondly, syringobulbia shows a predilection for this region, and it is important to point out a fact not generally known that syringobulbia may occur in apoplectic attacks These attacks are a form of progression of the disease, each one adding to the extent of the involvement Furthermore, syringobulbia is as a rule associated with some syringomyelic cavities in the cord, a pathologic process that will find expression in a more varied symptomatology

Thirdly we would particularly call attention to the bulbar type of poliomyelitis, which may come on with apoplectic suddenness, involving also one side of the medulla Here the usual elevation of temperature, characteristic changes of the spinal fluid and perhaps also some spinal cord involvement will readily help one out of the dilemma

Of other disorders that may occur in this locality we believe no mention need be made

The following case reports, two of them with autopsy material will serve to illustrate this syndrome

CASE 1—B K, a man, aged 67, admitted to the hospital, Dec 15, 1932, had been subject to attacks of angina pectoris for several months One morning a few days prior to admission he awoke with an attack that was diagnosed as a mild

Fig 3 (case 2)—Recent encephalomalacia and hemorrhage in the lateral corner slightly reduced from a photomicrograph with a magnification of 5 diameters

coronary occlusion After prompt medical aid he felt much better but was advised by his physician to remain in bed He felt so well however, that he got up and went to work the same afternoon

At noon that day while he was at lunch he suddenly felt dizzy and faint and had to be taken home to bed He vomited repeatedly had difficulty in speaking and complained of trouble in his throat The next day he was unable to swallow and his physician thought that a fish bone might have become lodged in his throat at lunch the previous day He was taken to the hospital for roentgen examination of the throat and

esophagus During the examination it was found that the barium sulphate stuck in the pharynx and did not move beyond it

A neurologic examination then revealed the following

1 Rotary nystagmus of the first degree was found, which affected each side but was more marked to the left

2 Marked hypesthesia of the left side of the face was present with an absence of the left corneal reflex

3 The soft palate on innervation was pulled to the right the so-called curtain movement

4 The sensation of the soft palate and pharynx on the left side was gone, so that the examiner's finger when introduced into the patient's throat on this side, fell into the depth as if into a hole, without meeting any resistance

5 Several areas of diminished sensitivity to pain and temperature were found on the right side of the body

The diagnosis was occlusion of the left posterior inferior cerebellar artery probably as the result of an embolus, which originated from a mural thrombus in the left ventricle of the heart

CASE 2—J P N, a man, aged 52, was a private patient of an outside physician and the record is incomplete However, the patient died while in the hospital and an autopsy was held here It is because of the instructive autopsy material that we decided to include the case with our presentation

The patient was admitted first Feb 26 1929 because of high grade cardiovascular disease with a recent onset of cardiac failure He showed no neurologic signs or symptoms at the time of his first admission Abnormalities then were confined to the evidences of cardiac failure He showed a moderate hypertension (156 systolic, 106 diastolic) and an enlarged heart with a systolic murmur at the apex At the time of the first admission he was kept in the hospital for two weeks treated for his failure and discharged March 12 as improved A week later he was readmitted because of the sudden appearance of evidences of a cerebral vascular accident Severe headache developed, and then he suddenly found that he was unable to swallow and noticed some difficulty in speech The record discloses no further details The examination as recorded revealed (1) right facial weakness, (2) moderate deafness (3) slow pulse (about 60) (5) hoarseness and (5) difficulty in swallowing

His condition became progressively worse and he died, March 28 one week after the vascular accident

The laboratory work and serologic reaction in this case were negative.

Although the clinical summary is meager, we think the pathologic demonstration will prove of considerable interest The gross specimens and the slides showed the sharp localization of the lesion to the lateral portion of the medulla We are sure that a careful neurologic examination would have revealed the syndrome as we have previously outlined it

CASE 3—B T a woman aged 31, married, admitted April 9, 1933 complained that on the previous night she awoke suddenly with a feeling of choking breathlessness, inability to swallow, numbness on the left side of the body and a tendency to fall toward the right side. The patient had a developed mitral stenosis She had been in the hospital only a month prior to this admission for a therapeutic abortion and sterilization Following this operative procedure a sudden cardiac failure developed with pulmonary edema She was treated for this condition remained in the hospital for about three weeks improved quite rapidly and at the time of her first discharge felt entirely well She remained well then until the episode mentioned

She was examined by us the day after her second admission The patient was lying in bed with her eyes closed, because she

Fig 4 (case 3)—Gross appearance of the defect in the lateral corner of the medulla (magnification 1 1/2)

stated, she got very dizzy when she opened her eyes. The following observations were made:

Examination of the cranial nerves revealed (a) Horner's syndrome on the right, (b) hypesthesia of the right cornea, (c) horizontal nystagmus of the first degree to the left and first and second degrees to the right, (d) suggestion of a facial weakness on the right, side of the central type, and (e) palatal weakness on the right side and a marked hypesthesia of the right soft palate and pharynx.

The upper extremities were essentially normal.

The abdominal reflexes were weak on the right and active on the left.

The lower extremities were essentially normal.

Fig. 5 (case 3)—Old encephalomalacia and defect in the tissue of the lateral corner of the medulla. $\times 5$

Sensory examination showed a hypesthesia for pain and thermal sense on the entire left side of body including the trunk and the extremities and a hypesthesia of the face on the right side.

We felt that we were dealing here with a cerebral accident and since the patient had a mitral stenosis with fibrillation the most likely cause was an embolus. The neurologic examination revealed involvement of the fifth seventh eighth ninth and tenth nerves on the right side and a hemihypesthesia of the left side of the body. This would localize the lesion in the right lateral portion of the medulla. Thus the diagnosis was occlusion of the right posterior inferior cerebellar artery, most likely as a result of embolism.

Except for the cardiac lesion, the rest of the examination was negative. The laboratory work and serologic reactions were all essentially negative. She improved remarkably from day to day and was discharged at the end of two weeks feeling very much better.

The patient was readmitted July 18, 1934, fourteen months after her attack of occlusion of the posterior inferior cerebellar artery, with a severe degree of cardiac failure and a recurrent rheumatic fever.

She was in the hospital for more than four weeks and her condition grew worse despite all treatment.

Neurologic examination showed that the nystagmus and the sensory changes were just as marked as they were at the time of the cerebral accident but that the other signs had cleared up.

The patient died August 23, with acute pulmonary edema and infarction of the right lung. In addition to the usual changes resulting from repeated rheumatic attacks there was found in the medulla the precise lesion which was clinically postulated some fourteen months before.

AIR IN THE BILE PASSAGES

A REVIEW AND REPORT OF A CASE

SAMUEL CANDEL, M.D.

AND

WILLIAM L. WOLFSON, M.D.

BROOKLYN

Biliary fistula into the intestinal canal usually results from the combination of infection and calculi in the biliary passages. Less frequently it follows a malignant condition of the gallbladder. Seldom does it develop from a perforating duodenal ulcer.

With all intra-abdominal inflammatory processes an attempt is made by the adjacent viscera to wall off the offending structure. When suppuration of the biliary tracts occurs adhesions form, and the gallbladder or its ducts may become agglutinated to proximate organs, i. e. duodenum, colon, stomach. As a consequence of constant pressure of calculi and advancing necrosis of the wall of the gallbladder, perforation into an adherent viscus may ensue. Internal biliary fistulas have frequently been associated with the presence of stones. Judd and Burden¹ found them to be present in the gallbladder or its ducts in 121 of their 153 cases. In 1885 Murchison² reported carcinoma of the gall

Fig. 1—Barium enema. Tab of barium is visible in the lumen of an air-containing viscus. The barium is also seen in the fistulous tract.

bladder to have been present in six out of nine cases of fistula between the gallbladder and the colon. Carman and Miller³ cited an instance of a carcinoma of the pylorus of the stomach that perforated into the gallbladder with the formation of a fistula. Kantor and

Jaffin⁴ and Lönnerblad⁵ recorded cases of perforation of duodenal ulcer into the gallbladder or its ducts. The formation of a self made anastomosis between the gallbladder or its ducts to the intestinal tract is not uncommon.

In 1909, Robson⁶ demonstrated at operation a calculus impacted in a freshly forming fistula between the gallbladder and the colon. Judd and Burden referred in their series to eleven cases in which a stone was found in transit in the lumen of the fistula. Lönnerblad described a case of cholecyst-intestinal

Fig. 2—Y shaped gas shadow outlining two hepatic ducts and the common bile duct

fistula without any history of abdominal colic. He indicated two similar instances, one reported by von Korte and the other by Graeberger⁷. Here it must be assumed that, owing to an eroding stone, perforation took place slowly and that the inflammatory reaction was minimal. This is extremely rare.

Of 10,866 autopsies reported by Roth, Schroeder and Schloth,⁸ only forty-three fistulas between the gallbladder and the intestinal canal were found. Naunyn⁹ and Courvoisier collected 384 cases of biliary fistulas, of which 184 were of the cholecystogastro-enterocolonic type. Judd and Burden at the Mayo Clinic reported a large group of cases of internal biliary fistulas disclosed at operation. In these series, the most common by far were the cholecystoduodenal fistulas. Then next in order of frequency were the cholecystocolonic, cholecystogastric and, least frequent, the cholecystoduodenocolonic fistulas.

At operation or postmortem examination, the gallbladder is usually small and fibrotic. Stones are generally present. Often the common duct is greatly dilated. The liver may show cirrhotic changes or a thickened capsule.

The impaction of a stone in the duodenum or small intestine complicating the perforation of the gallbladder into the digestive tract, may result in intestinal obstruction. Stones that have perforated into the large bowel rarely produce obstruction unless the stone is enormous or unless conglomerated calculi have formed a large mass. Retrograde infection from colon fistulas has resulted in abscess formation of the liver.¹⁰

Although the literature is replete with references to internal biliary fistulas, only forty-three cases have been diagnosed preoperatively. Masciottra and Etcheverry¹¹ reported one case. Lönnerblad described two personally observed cases and cited forty collected from the records. Judd and Burden reported that in their series of biliary fistulas, the diagnosis was made but twice. Of the forty-three cases diagnosed, six were cholecystocolonic fistulas (Reich,¹² Lönnerblad, Fuller,¹³ Judd and Burden (two cases), and Schinz¹⁴). The cases of Judd and Burden and of Schinz were proved. We wish to add our case to those previously reported as diagnosed before operation and confirmed at operation.

Of great interest in the case which we present is the display of gas shadows in the bile passages. This has been observed only six times in spontaneous internal fistulas (von Friederich,¹⁵ Öhnell and Lindblom,¹⁶ Graeberger Busi,¹⁷ Alberti¹⁸ and Beutel¹⁹) and three

Mallet-Guy and Beaupère,²¹ and Odischaria²²) In von Friederich's case the actual spirals of the valves of Heister were perfectly outlined by gas. In our case, the colon, the fistula, the small gallbladder, the cystic duct, the dilated common duct and the hepatic ducts were air filled and clearly visualized.

REPORT OF CASE

History—P. D., a housewife aged 41, the mother of four children, entered the hospital Dec 10, 1934. After her 1st pregnancy eight years previously she suffered an attack of upper abdominal pain below the costal margin and slightly to the right of the midline. The pain was very sharp in character, radiated around the right costal margin to the back and to the right shoulder region. During the attack she was nauseated and vomited thick green material. Fever of unknown height occurred during the first three days. After three weeks of illness all symptoms suddenly subsided. No jaundice or chills were present.

For five years after the initial episode, attacks of distressing abdominal pain recurred. They were referred to the upper right quadrant and were prone to follow the ingestion of

four minutes and bleeding time was two minutes. The blood chemistry was normal. The Wassermann and Kahn tests were negative.

Stool examination revealed no ova or parasites, and no blood. A small amount of undigested material and an occasional white blood cell was present. Some yeast cells were seen.

A barium enema revealed an abnormal oblique smudge like shadow in the upper right quadrant above the hepatic flexure and toward the transverse colon (fig 1). A trickle of barium had apparently passed out of the colon into a hollow structure filled with air lying externally to and diagonally above the hepatic flexure. The structure was interpreted as being the common bile duct.

The stomach and duodenum were roentgenographically normal. However, there was observed a Y-shaped air shadow with the lower vertical line lying slightly diagonally to the long axis of the abdomen and medially to the superior portion of the duodenum (fig 2). Gas had evidently outlined the common bile duct and the two hepatic ducts which emptied into it.

A flat plate of the abdomen visualized air shadows which outlined the fistula leading from the colon into the gallbladder, the cystic duct, the dilated common duct, the hepatic ducts and smaller biliary radicles (fig 3). A cholecystogram failed to outline the gallbladder (a usual occurrence in gallbladder fistula).

The preoperative diagnosis was cholecystocolonic fistula.

Operation—There was observed a small gall bladder about 3 inches long and three fourths inch wide, grayish, fibrotic, thick walled and noncaliculous. The organ was adherent both to the liver which was scarred and cirrhotic around the gall bladder area and to the transverse colon, to which the fundus was joined. The left lobe of the liver was normal. The head of the pancreas was slightly thickened. The common duct was dilated 1½ inches in diameter. The appendix was moderately fibrosed.

After many dense adhesions had been cleared from the area of the hepatic flexure it was possible to view a union of the fundus of the gallbladder to the transverse colon (fig 4a). This bridge was severed between clamps and an enterorrhaphy was done to close the defect (stoma opening) of the colon (fig 4b). The fistulous opening was 0.5 cm in diameter. A cholecystectomy was easily performed. The dilated common duct was investigated and found to be free from detritus. It was then drained with a large catheter. The appendix was removed.

The pathologic report was chronic ulcerative cholecystitis and chronic appendicitis.

Since her operation of three months ago, the patient has been absolutely symptom free for the first time in two years.

CONCLUSIONS

1 In a case of spontaneous cholecystocolonic fistula roentgenographic studies demonstrated gas and barium shadows in the biliary passages.

2 Persistent cramps and diarrhea were outstanding and significant symptoms.

3 The diagnosis was made preoperatively and confirmed by operation.

3021 Avenue I

Abuse of Language Mechanism—The language mechanism is, however, so easy for all to employ, words are so cheap sentences are complete grammatical units, and hence a speaker or writer may meander along without end or aim in his recording of nonrelated word-complexes. The worst that can be said of them apart from their futility, is that they are harmless so long as they do not lead to the acceptance of correlation between statements which are merely juxtaposed.—Bolton, J. S. The Evolution of Mind *Lancet* 1 728 (March 30) 1935.

Fig 4—*a*, anastomosis of the fundus of the gallbladder to the colon; *b*, division of the union between clamps.

fatty or fried foods. During this time she was frequently constipated.

For the past two years she complained bitterly and persistently of the almost daily occurrence of cramps associated with diarrhea. The cramps began in the right hypogastrium radiated downward and then became generalized in the abdomen. The stools contained mucus but no gross blood. Weakness had been progressive.

The past history other than that mentioned was immaterial.

Physical Examination—The abdominal wall was moderately thick but was not distended. There was no enlargement of the liver or spleen. In the upper right quadrant there was noted deep elastic resistance and some tenderness. No other significant changes were present.

The temperature, pulse and respiration were normal. The blood pressure was 116 systolic 88 diastolic.

Laboratory data revealed the following. The urine was normal. The red blood cell count was 3,600,000, hemoglobin estimation 70 per cent. The white blood cell count was 6,750 with 80 per cent polymorphonuclear leukocytes, 19 per cent lymphocytes and 1 per cent mononuclear cells. Coagulation time was

THE HAZARDS OF THE INDUCTION
OF PNEUMOTHORAX

IN THE TREATMENT OF LOBAR PNEUMONIA

JESSE G M BULLOWA, MD

AND

EDGAR MAYER, MD

NEW YORK

Pneumothorax is being used in many hospitals as a therapeutic measure in lobar pneumonia. Conflicting reports concerning the efficacy of this procedure have appeared in the literature. Its proponents present dramatic though uncritical results that are apt to stimulate undue enthusiasm. It seems well at this time to put forward a word of caution. Pneumothorax may be a hazardous procedure, and at present insufficient data to recommend its use are available.

The lobar pneumonias are a group of diseases due to different organisms which display more or less distinctive characteristics in respect to age incidence, course and prognosis, depending on the etiologic agent. The most important element determining the outcome in these diseases is the occurrence and degree of blood invasion. Pneumococcal pneumonias that do not become blood invaded have a mortality of 12 per cent or less, those blood invaded have a mortality of 25 per cent or more. In 139 nonbacteremic type I cases treated with serum on the first three days there were five deaths, a mortality of 3.6 per cent, in thirty-three blood-invaded cases the mortality was 33.3 per cent. Without serum the lowest mortality reported in the literature for type I cases is 20 per cent. The various pneumococcus types have blood invasion rates and mortalities that closely approach one another but are different for each type. The experiments of Stillman¹ and of Tuttle and Cannon² showed that damage to the lung capillaries

due to the character of the invading organisms was the determining factor in blood invasion. Spontaneous recovery from pneumonia is apparently due to the development of humoral immunity. Recovery may be therapeutically induced by the passive transfer of this humoral immunity when administered sufficiently early in cases for which an antiserum is available. Delay in administration of type I serum increases mortality, as shown in the accompanying table.

MODE OF ACTION

Artificial pneumothorax has been proposed by its advocates as a natural surgical method of placing the lung at rest, some using for analogy the benefits accruing from splinting an infected hand to avoid spread and blood invasion. Although it is recognized that with increasing degrees of collapse there is a corresponding reduction in the blood volume flow through the collapsed lung and that it is probable that there is a reduction in the lymph drainage from the collapsed lung, yet despite the remarkable healing of tuberculous lungs incident to pneumothorax therapy and despite the long years of use we do not know what part these physiologic alterations play in the healing process.

LIMITATIONS AND HAZARDS

There are certain limitations and hazards involved in the use of pneumothorax in lobar pneumonia. It is

Fig 1—Frequency of empyema in serum treated pneumococcal pneumonia type I. Influence of day of initial serum treatment. Figures above plain columns indicate the number of serum treated cases. Figures in shaded columns cases of empyema. Percentage frequency is indicated on ordinate.

apparently recommended only in the early cases. Later in the disease, when well established consolidation has occurred, pneumothorax cannot collapse the consolidated lung. Patients with bacteremia, either early or late in the disease, do not respond favorably. Collapse of uninvolved lung may aggravate the dyspnea in a patient whose demand for oxygen is already increased by reason of fever and the mixture of unoxidized with oxidized blood. No one can selectively collapse the involved lobe. It may remain uncollapsed though the normal lobe shrinks. The introduction of air into an inflamed pleural sac presents conditions favorable to the development of fluid that may become purulent. Separation of the pleural surfaces precludes the localization of empyema should it occur as a spontaneous complication. When administered sufficiently early, serum therapy for type I reduces the incidence of empyema, as is shown in figure 1. Experience thus far indicates that a surprisingly large number of cases

present an adhesive pleurisy over the diseased lobe which precludes satisfactory collapse, when discovered pneumothorax therapy should usually be abandoned. Traumatic rupture of the lung and air embolism are complications that have occurred. Infected nucus may be forced into the opposite lung, and in some cases rapid development of a contralateral pneumonia has occurred notwithstanding the induction of pneumothorax. Elderly people with reduced vital capacity or those with cardiovascular diseases have likewise not done well.

The other has elected for treatment thirty cases from his service at Harlem Hospital.

The following complications and disadvantages have been noted with pneumothorax therapy of pneumonia

- 1 Late invasion of the blood stream in spite of collapse.
- 2 Invasion of another lobe on the collapsed side.
- 3 Invasion of the contralateral side.
- 4 Empyema
- 5 Induced rupture of the lung
- 6 Extreme mediastinal shift, with death
- 7 Harmful delay in application of serum therapy to suitable cases, as evidenced by unusual complications—nephritis

Fig 2—Condition on admission Feb 26, 1935 at 3 p m showing the involvement of the right lower lobe. The left lung field is clear.

Fig 3—Condition after attempted induction of pneumothorax showing clear lung field, 150 cc of air introduced; no pressure reading obtained; no relief of pain.

Fig 4—Appearance after the third refill and introduction of 950 cc. of air with collapse of right lower lobe which however, is much more dense than in the previous film. Readings with left lateral recumbent posture: -4 +1 1/2. There is commencing involvement of the upper portion of the left lower lobe without hilar involvement. The pain was relieved after the introduction of 375 cc of air with a resultant pressure reading of -3 +1.

TECHNIC

Absence of standard technic shows that the therapy is still in the experimental stage. Certain workers have instituted only one, two or three treatments at intervals of twelve, twenty-four or forty-eight hours. Some employ frequent refills at intervals of from three to four hours to attain speedy collapse. Some use negative intrapleural pressures. Others desire that pressures be slightly positive.

To evaluate this therapeutic procedure one must have frequent roentgen and accurate bacteriologic and

8. Fatigue of patients by frequent manipulation and roentgen examinations.

CONCLUSIONS

There is insufficient evidence to warrant the use of artificial pneumothorax in the treatment of lobar pneumonia except in large hospitals amply equipped for bacteriologic, serologic and roentgenographic studies.

Pneumothorax therapy should not be employed by those inexperienced in the treatment of pneumonia or in the use of artificial pneumothorax.

The favorable results thus far recorded deal almost solely with patients in the early stages of the disease and without bacteremia, and in pneumococcus types that otherwise have a low death rate. Prevention of bacteremia in patients has not been demonstrated. The response of dogs to pneumococcus type III is quite different from the response of patients.

The use of artificial pneumothorax in pneumonia is still in the experimental stage. Until a sufficiently large number of cases have been studied, general practitioners are not justified in employing it.

At least all cases of type I, as well as those of type VII and early cases of type II, should receive serum. In them the hazard of pneumothorax appears unnecessary.

Even those advocating this therapy do not recommend it for patients with well established consolidation, patients with bilateral lesions and those appearing for treatment after the third day of the disease.

REPORT OF CASE

W W a Negro aged 26, admitted at 12 45 p m, Feb 26 1935, to Harlem Hospital complained of midsternal pain, a cough and fever since February 24. At 8 p m on that day he had severe chest pain aggravated by difficulty in inspiration.

Fig 5—More extensive involvement of the upper portion of the left lower lobe at this time with a selective collapse of the right lower lobe and failure of the right upper lobe to collapse completely. A small amount of fluid is seen in the right pleural cavity. Pressure readings at this time: -4 +1.

Fig 6—Reexpansion of the lung. Entire clearing of the left lower lobe with increased markings persisting in the right lower lobe which had been collapsed.

serologic studies, and in view of the multiplicity of types a sufficient number of early cases to study. Early termination of a pneumonia and relief of clinical symptoms in any single case is not evidence of benefit achieved by the therapy. Some cases terminate early with no treatment and to indicate a change in the usual duration it must be shown that this occurs regularly in a large series.

One of us has observed sixteen cases with five deaths (30 per cent) and three empyemas (18.7 per cent).

with the cough becoming worse. The following morning he had a chill and blood tinged sputum.

On admission he had moist rales throughout both lungs and diminished breath sounds at the right base, with dullness. The pulse was 136, the respirations were 44 and the temperature was 104 F. The white blood cell count was 26,400, polymorphonuclear leukocytes 85 per cent. Figure 2 shows a consolidation in the lower portion of the right lower lobe, the remainder of the lung fields were clear. The sputum revealed pneumococcus type I.

At 3 p. m. a pneumothorax was performed with the administration of 150 cc of air. A roentgenogram (fig. 3) taken after this pneumothorax showed a slight amount of air below the consolidated lung. At 8 p. m. the temperature and pulse fell, the pulse being 114, the temperature 100 F and the respirations 36. At this time 375 cc of air was administered. The pressure reading changed from minus 5 minus 1 to minus 3 plus 1 and there was considerable relief of pain. At 11:45 an additional 425 cc of air was administered and the

patient was discharged cured on the fifteenth day with the lung fully expanded though there was still some radiopacity at the site of the original pneumonia, which had been collapsed. The second invasion had entirely cleared.

Though it is possible that the invasion of the contralateral lung was the result of the collapse of the primary site, this is by no means established or urged. It is more probable that the second invasion developed as the result of the pneumococcal infection which was unchecked by the induction of pneumothorax. Obviously the treatment of the opposite side by pneumothorax was impossible.

Without roentgen study of the progress of the infection and prompt recognition of an invasion of the contralateral side and typing, this patient would not have received the benefits of serum therapy. At least from eight to twenty-four hours would have been necessary to determine whether the blood culture was positive. The induction of pneumothorax in this instance was an unnecessary, costly and dangerous therapeutic interference which was responsible for delay in administering specific therapy.

Clinical Notes, Suggestions and New Instruments

MIGRATION OF NEEDLE INTO HEART THROUGH CHEST WALL SURGICAL REMOVAL

ELECTROCARDIOGRAPHIC AND ROENTGENOGRAPHIC STUDIES

HAROLD A. GOLDBERGER, M.D. AND HAROLD E. CLARK, M.D.
NEW YORK

This case is reported because of its unique character and its interesting electrocardiographic and roentgenographic records.

N. S., a man aged 34, Puerto Rican sign painter, was brought to the Metropolitan Hospital by ambulance, complaining of pain in the left side of the chest. He stated that he was sleeping in a bed placed directly below a pincushion suspended on the wall. He was aroused from sleep by a sharp pain in the anterior part of the left side of the chest. He said it felt as if a needle had stuck him. The pain increased in intensity and he called an ambulance.

On admission of the patient to the ward the pain had increased in severity and was exaggerated on deep breathing. He now complained of pain radiating to the tip of the left shoulder and designated the tip of the acromion process and the area covered by the supraclavicular fossa in addition to the precordium as the points of maximum pain.

The past and the family history were of no significance except for the fact that he had been admitted to the hospital on two previous occasions for acute alcoholism. At the time of the previous admissions no pathologic condition was found other than the acute alcoholism, no cardiac murmurs and no arrhythmia or abnormal changes in blood pressure.

On physical examination the patient was sitting up in bed apparently in acute pain and slightly dyspneic. The pupils reacted to light and distance. No abnormal pulsations were present in the neck. Expansion of the two sides of the chest were equal. On the left anterior chest in the fourth interspace $1\frac{1}{2}$ inches medial to the nipple line was a small red point about 1 mm in diameter. This area was tender only on deep pressure. The lungs were resonant throughout and no rales were heard.

The border of the left ventricle was percussed for a distance of 8.5 cm from the midline. The apical impulse was seen and felt in the fourth interspace 8 cm from the midline. A coarse thrill was palpated all over the precordium maximal

From the Department of Surgery, Metropolitan Hospital, Service of Dr. Lucius Salisbury.

Fig. 7.—The temperature chart of patient W. V. suffering from pneumonia due to pneumococcus type I involving the right lower lobe. After good collapse of this lobe there was an involvement of the left lower lobe commencing at its apex and with rise of temperature to 106 F. At this time large doses of pneumococcus type I serum were given with fall of temperature and pulse to normal.

pressure readings were minus 4 plus $1\frac{1}{2}$. During the night the temperature rose to 106 F and the pulse, which had reached 130 was 118. Another roentgenogram taken during the night showed a well collapsed right lower lobe, a partially expanded right upper lobe and a definite involvement in the central portion of the left lung field. There were signs of consolidation in the upper portion of the left lower lobe.

On admission studies of the agglutinins for type I prior to the administration of specific serum for type I had been negative. On the evening of the second day in the hospital and during the night, four doses of serum were given at the following times: 6:30 p. m. 10,000 units; 9:45 p. m., 67,500 units; 1 a. m. 135,000 units and 5 a. m. 67,800 units.

The temperature and the pulse reached normal. Agglutinins were strongly evident in the blood stream. There was no significant rise of temperature until the eleventh day when the patient had a mild serum sickness lasting three days. The

at a point 1 cm medial to the site of the pin prick. On auscultation both heart sounds were obscured by a very loud, coarse, grating murmur, which reached maximal intensity during systole. The same ill defined noise was still further intensified with each respiration. All other physical manifestations were normal.

The temperature was 99.8 F, the pulse was regular, was of good quality, was equal at the two wrists and maintained a rate of 92, respirations were slightly labored at a rate of 24, blood pressure was 108 systolic, 85 diastolic. Urinalysis showed a specific gravity of 1.034, a faint trace of albumin, absence of sugar, a moderate number of white cells and an occasional hyaline cast.

twelve hours after the operation the patient's respiration became labored and the pulse rapid and weak. Respirations were 36 per minute, the pulse was 160 and the blood pressure 80 systolic, 64 diastolic. Examination of the chest showed dullness and absent breath sounds at the left base. Examination with a portable x-ray apparatus showed fluid in the left side of the chest with shifting of the heart slightly to the right. There was no collapse of the upper left lung. Pleural puncture was done on the left side and 300 cc. of dark fluid blood was removed. In spite of supportive measures the patient's condition became rapidly worse, blood pressure was 60 systolic, 40 diastolic, the respiration rate 42 and the temperature 103. The patient died a short time later.

Fig 1—Routine chest plate showing the needle in the third interspace in the shadow made by the left ventricle

Fig 2—Exposure with the Bucky diaphragm showing the needle casting several shadows owing to contraction of the left ventricle

Fig 3—Chest plate taken after operation showing enlargement of the heart shadow (hemopericardium) and early pneumonia (atelectasis) at the right base.

A diagnosis of needle in the heart was made and the patient was taken to the x-ray room, where two exposures were made, one a routine chest plate and the other an exposure with the Bucky diaphragm (figs 1 and 2).

With fluoroscopic examination the needle was visualized as a straight body about 2 inches long moving with each systole in an oblique direction in a plane parallel to the third interspace about an inch from the midline. The position thus found was mapped out on the chest with a skin pencil.

An electrocardiogram was taken (fig 4) and the patient was prepared for the operating room. Nitrous oxide-oxygen-ether anesthesia was given. The operative procedure consisted of a vertical incision made from the third rib to the sixth rib in the left parasternal line with a horizontal incision along the fourth intercostal space for a distance of 7.5 cm. The fourth and fifth costal cartilages were incised and the intercostal muscles of the fourth interspace cut. The parietal pleura was opened and no free fluid was found but a few very fine threads of fibrin were seen to stretch with each heart movement between the parietal pleura and the pericardium. The pericardium was examined but not opened, and no evidence of hemorrhage was seen. The eye of the needle was located by palpation and then visualized in a plane parallel to the third interspace. The only portion seen was the eye proper the remainder being buried in the left ventricle.

On close examination the needle was seen to have passed through the lower medial tip of the upper lobe of the left lung at the cardiac incisura and at this point a small laceration one-half inch in length was seen in the lung tissue. The needle was withdrawn with a curved hemostat and found to be 1 3/4 inches long. At this time no bleeding in the heart tissue was observed and it was quite interesting to note that the site of perforation was very close to the left coronary artery. The pleura was then closed and the intercostal muscle sutured approximating the costal cartilages. The skin was sutured with black silk.

The patient returned from the operating room to the ward with a pulse of 110 and in relatively good condition. The first ten hours after operation was uneventful the patient resting comfortably under the usual postoperative sedation. About

Postmortem examination of the wound revealed the pericardial cavity full of dark red fluid blood. There was a deposit of fibrin over the heart and the puncture wound was clearly seen in the left ventricle.

SUMMARY

- 1 In the case here reported roentgen examination confirmed the clinical diagnosis of a needle in the heart. An exposure made with the Bucky diaphragm showed the interesting phenomenon of a needle in the left ventricle causing several shadows as a result of the contractions of the left ventricle.
- 2 An electrocardiogram showed the unusual phenomenon of an artificially produced coronary syndrome with high take-off

Fig 4—Electrocardiogram taken before operation showing a high take-off of the T wave in leads 1 and 2 and inversion of the T wave in lead 3. With a rate of 100 the PR interval was 0.12 second and the QRS interval was 0.4 second. The auricular and the ventricular rhythm were regular.

of the T waves and inversion of the T wave in lead 3. The pain distribution was that of coronary artery disease and the site of the needle puncture in the left ventricle was close to the proximal portion of the left coronary artery.

3 Postoperative roentgenograms showed enlargement of the cardiac shadow with apparent fluid in the pericardial sac clouding of the left base of the pulmonary field and rapid reexpansion of a lung artificially collapsed during operation. The patient apparently died of secondary hemorrhage into the pericardial sac and subsequent cardiac tamponade.

RETROPERITONEAL LIPOMYXOSARCOMA

CARRINGTON WILLIAMS M.D. RICHMOND VA

There is no more innocent new growth than the ordinary pure lipoma. When, however, there are areas of fibrous or myxomatous tissue scattered throughout the tumor it has a tendency to recur and not infrequently to change from a benign to a malignant tumor. This malignant tumor is a sarcoma arising from the fibrous tissue, which recurs locally without metastasis to distant parts of the body.

The case reported is interesting first on account of the enormous size of the tumor, secondly because the original tumor appeared benign and thirdly because of the changes in the character of the tumor and in its microscopic appearance at three different times during a period of six years.

REPORT OF CASE

Mrs F N J, a widow, aged 65, who had enjoyed excellent health until the onset of her present trouble entered St Luke's Hospital June 22, 1925. Four years before she first noted a mass in the right side of the abdomen. There was no pain or other discomfort associated with this mass until after two years, when it had grown quite large, there was discomfort from the weight of the tumor and attacks of weakness. At

Fig 1—Tumor removed at first operation. The kidney is seen in about the middle of the lower portion.

this time the tumor was explored (at another hospital) without the peritoneal cavity being opened. It was considered irremovable and tissue was taken for microscopic examination. This tissue was reported lipoma. Several roentgen treatments were given without effect on the tumor. She continued to lose body weight and strength, but the tumor continued to grow so that on admission to the McGuire Clinic her combined weight equaled her maximum weight. The atrophy of her body was due to the growth of the tumor because her appetite was enormous.

Physical examination, aside from the huge tumor which filled the abdomen from ribs to pelvis, showed large tortuous veins over the anterior chest, a systolic mitral murmur with slight hypertrophy of the heart and edema of both legs.

The blood Wassermann reaction was negative. Urinalyses were not significant. The blood showed red cells 2,760,000; hemoglobin 40 per cent (Dare); white blood cells 6,000; polymorphonuclear leukocytes 78 per cent; lymphocytes 20 per cent; large mononuclear leukocytes 1 per cent; and eosinophils 1 per cent. Four transfusions of whole blood were given, resulting in a rise of hemoglobin to 60 per cent. Her general condition was likewise improved.

Operation was performed July 2 by Dr Stuart McGuire and myself. A long incision was made over the tumor which

was exposed without the peritoneal cavity being entered. It separated from surrounding structures with remarkable ease until the whole mass was lifted upward, exposing the right renal vessels. The kidney was so deeply embedded in the tumor that it was removed in situ. During the dissection the peritoneal cavity was opened. The entire intestinal tract and peritoneal cavity were pushed well over to the left side. There was no tumor in the cavity. The peritoneum was closed. The tumor apparently had been completely removed. A large drain

Fig 2—Section of the tumor removed at the first operation showing fat and fibrous tissue.

of gauze and rubber was inserted into the cavity and the wound closed around it. The tumor was made up of fat and fibrous tissue and weighed 51 pounds (23 Kg) (fig 1). Microscopically it was largely pure fat but some areas showed a preponderance of fibrous tissue (fig 2). The diagnosis was fibrolipoma (Dr S W Budd). Convalescence was smooth, disturbed only by a moderate amount of bloody discharge. The lowest hemoglobin after operation was 46 per cent. The body weight three weeks after operation was 82 pounds (37 Kg).

Fig 3—Section of the tumor removed at the second operation.

At this time the edema of the ankles had cleared up and the dilated veins on the anterior chest wall had disappeared. The patient gained rapidly in weight and strength and returned to her former strenuous activities. Six months after operation she weighed 122 pounds (55 Kg) and after a year 132 pounds (60 Kg).

She remained well and active for five years when she noted a mass in the right flank. This increased in size so she returned for treatment June 2, 1930. At this time she was well nourished, the tumor mass was movable and lobulated.

and aggregated about the size of an adult's head. The phenolsulphonphthalein excretion was 36 per cent in a two hour period, the nonprotein nitrogen of the blood was 36 mg per hundred cubic centimeters and sugar 110 mg. The hemoglobin was 70 per cent.

She was operated on June 8. The peritoneal cavity was opened and innumerable pedunculated firm growths were found scattered throughout the right side of the cavity, varying in size from 1 to 10 cm in diameter. The great omentum was heavily infiltrated and behind the peritoneum were two masses about 12 cm in diameter. The omentum was resected as many of the pedunculated growths were removed as was possible and the large retroperitoneal masses were removed.

Some of these tumors were pure fat others were myxomatous and still others were more fibrous in character with areas showing definitely malignant change (fig 3). The diagnosis was lipomyosarcoma (Dr Budd).

Following the operation the patient improved but was never well again. In January 1931 a recurrence of the growth was noted but at this time she had had fever over a period of several weeks and was not able to return to the hospital until May. She now had lost weight and strength and appeared quite ill. There was a hard immovable mass in the right side of the abdomen extending from the ribs to the pelvis. The

Fig. 4—Section of the tumor removed at the third operation

hemoglobin was 46 per cent nonprotein nitrogen of the blood 36 mg, creatinine 1.8 mg, and sugar 125 mg. Phenolsulphonphthalein excretion was 22 per cent in a two hour period. At operation this mass consisting of two large nodules measuring 12 and 20 cm in diameter was removed.

The microscopic examination by Dr Budd revealed much the same picture as before, except that the areas of sarcoma now predominated and the cells were more highly malignant (fig 4).

The patient made a good recovery from the operation but did not regain her former strength. Recurrence of the tumor was noted five months later and after another month she died six years and four months after the removal of the tumor and ten years after it was first discovered.

COMMENT

The original biopsy specimen taken two years after discovery of the tumor showed a pure benign lipoma but it was probable that the tumor at that time would have shown its fibrolipomatous character had it been completely removed. It was certainly originally benign. The tumor was exposed to x-radiation (amount not known) without any favorable influence. It is interesting to speculate on the question of actual harm that the rays may have done. These large retroperitoneal lipomas usually recur as sarcomas, it is therefore important to remove them early and completely. Since the recurrence is only local

repeated operations should be done as radically as circumstances permit. A review of the literature of recent years fails to reveal a report of such a tumor as large as this one. The first tumor weighed 51 pounds the second and third tumors approximately 10 pounds each (4.5 kg), making a total tumor weight of about 70 pounds (31.8 kg).

THE TREATMENT OF CIRRHOSIS OF THE LIVER WITH INSULIN

JOHN E. WALKER, M.D., COLUMBUS, GA. AND WILEY D. WOOD, M.D., CAMP HILL, ALA.

Lepelne¹ states that the combination of a high carbohydrate diet and insulin is of value in the treatment of cirrhosis of the liver. McCabe and Hart² report five cases treated in this manner with a definitely favorable influence on the disease.

We have used this method of treatment in one case. The result was gratifying. A report seems desirable in an effort to stimulate further trial of the method in this generally hopeless disease particularly in ambulant patients not yet showing signs of hepatic toxemia.

A white man aged 48 unmarried a carpenter complained of a swollen abdomen March 1 1933. His past health had always been good except for malaria at the age of 18 years and gonorrhea at the age of 34. He had never had a venereal sore and stated that he did not use alcohol.

His present illness began fourteen months previously when the abdomen began to swell. This swelling gradually increased and had prevented him from working for four months. Shortness of breath had not been present at the onset of illness but had gradually developed with the progressive abdominal enlargement.

The patient was emaciated. There was no evidence of cardiac enlargement or valvular disease. The abdomen was enormously distended and there were enlarged tortuous veins over the lateral walls of the chest. There was moderate edema of the lower legs. The Wassermann reaction was negative.

Abdominal paracentesis was done April 1. Three gallons of fluid with a specific gravity of 1.010 was removed. Altogether he was tapped thirty-two times between April 1933 and May 1934. The intervals between tapings averaged twelve days. From 3 to 4 gallons of fluid was obtained at each tapping.

Soon after the patient was seen he was given five intramuscular injections of sahrgan. He took 15 grams (1 Gm.) of theobromine sodiosalicylate three times a day for twenty-two days beginning Sept. 26 1933. Following this he took daily 48 grams (31 Gm.) of ammonium nitrate for twelve days. Finally he took 240 grams (155 Gm.) of urea three times a day for sixty-one days (until Jan. 1 1934). None of these diuretics had any noticeable effect on the disease or on the frequency of tapping. Diuresis was evident, but the patient was apparently unable to control the ensuing thirst.

Dec. 15 1933 as a result of the appearance of the article by McCabe and Hart² insulin was begun at first 5 units before the noon meal. By December 28 this had been increased to 10 units three times a day before meals and on Jan. 12 1934 a further increase to 15 units three times a day was made. The last dose was continued until March 28 thus making a period of slightly over three months during which he received insulin.

During the period of insulin administration the patient followed a diet containing approximately 400 Gm. of carbohydrate. Except for a preliminary period of instruction he administered the insulin to himself. The danger of insulin reaction was strongly impressed on him, and he carried sugar with him at all times. No insulin reactions occurred.

Throughout the period of observation the patient was ambulant. He was his own judge in regard to when tapping was necessary requesting it when the abdomen became so distended as to impede his movements. Edema of the feet also subsided after each tapping.

² McCabe, John, and Hart, J. F. Treatment of Hepatic Cirrhosis with Insulin. New York State J. Med. 33: 924 (Aug.) 1933.

In February there was a period of seventeen days during which tapping was unnecessary. This was the longest interval without tapping since the first paracentesis eleven months before. Following this, two more tapings were necessary, the last one on May 20.

The patient was last seen in December. There was no evidence of fluid in the abdomen. He had resumed his occupation as carpenter. A recent letter (Feb 18, 1935) states that he is employed as the manager of a large farm and that he feels nearly as well as ever.

SUMMARY

A case of cirrhosis of the liver showed marked improvement on being treated with insulin and a high carbohydrate diet. Abdominal paracentesis, after having been necessary thirty-two times was discontinued altogether.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

PARATHYROID HORMONE THERAPY

JOSEPH C. AUB, M.D.

BOSTON

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed, the series will be published in book form.—ED

The clinical use of the active principle of the parathyroid gland is dependent on its marked influence on calcium and phosphorus metabolism. Its physiologic effects are, in brief:

- 1 To raise the blood calcium and lower blood phosphorus
- 2 Possibly to increase the ionized calcium in the blood
- 3 To increase the calcium and phosphorus excretion in the urine
- 4 To obtain the calcium for this increased demand either from a large amount of ingested calcium or from the stores in the bone

When given in excess, parathyroid extract elevates the blood calcium excessively and a train of toxic manifestations may occur:

- 1 The kidney is damaged and, possibly as a result,
- 2 Blood phosphorus rises and
- 3 Nitrogenous waste products accumulate in the body fluids
- 4 Abnormal deposits of calcium salts occur in soft tissues
- 5 Because of the large excretion of calcium and phosphorus in the urine, kidney stones are formed
- 6 Osteitis fibrosa cystica develops in bones, with an increase in activity of osteoclasts, and usually of osteoblasts. As a result, there appear generalized osteoporosis, cysts, and giant cell tumors

CLINICAL USE

It is apparent, therefore, that when used in the clinic the effect of parathyroid extract must be carefully watched in order to obtain an effect within physiologic limits. This can be accomplished by frequent determinations of the level of calcium and phosphorus in

the blood. A blood serum calcium level above 12 to 13 mg per hundred cubic centimeters is never desirable.

Parathyroid Dosage—It must be remembered that the strength of the unit of parathyroid hormone has been reduced recently to one fifth of its previous potency. The doses referred to in this paper, therefore, are expressed as the new 1934 revision of unitage, while the concentration of the extract and therefore the volume of injections remains unaltered. Like other active principles of glandular secretion, parathyroid extract has a greater effect when it is needed. Thus seventy-five units a day (1934 revision) may be enough to elevate the blood calcium level from 4.5 to 7 mg per hundred cubic centimeters of serum in a case of low calcium tetany. In normal individuals it may require 500 units a day to raise the level from 10 to 12 mg per hundred cubic centimeters of serum. However, the variation in susceptibility is great, and amounts that will markedly elevate the blood calcium in one individual may have little effect in another. The dosage must be regulated by determination of the level of blood calcium, repeated every few days until the new blood level is stabilized. When the doses are too small, this can of course be detected by continuance of the tetany, but hypercalcemia gives few clinical indications until a level of about 14 mg per hundred cubic centimeters of serum is reached. There then appear loss of appetite, nausea and a great sense of fatigue.

Collip showed that repeated doses of the extract are more effective than a single large injection. It is therefore wiser to give the parathyroid extract twice daily even though the injections cause some induration and pain.

Time Relations—Parathyroid hormone, injected intravenously, has a latent period of approximately four hours, after which the blood calcium rises and therapeutic effects begin. These effects then last about twenty hours following a single injection. In contrast to this it must be remembered that calcium salts when injected intravenously exert an immediately beneficial effect, which is often prolonged beyond two hours. Vitamin D, on the other hand, when given in very large doses, gradually elevates the blood calcium level over a period of days. This effect, when once established, is maintained for at least two weeks after therapy is discontinued. An overdose of vitamin D, therefore, is associated with loss of appetite and discomfort for a prolonged period.

Duration of Effect—The chief disadvantage of the parathyroid extract now available is the gradual loss of its effect. After several months of use an apparent immunity to it is established and then 750 units may produce no effect in a patient who originally responded well to 50 units. This characteristic limits its use to rather acute conditions, in which the treatment needs to be continued for weeks rather than months.

VITAMIN D IN RELATION TO PARATHYROID EXTRACT

Vitosterol, when given in large enough amounts, exerts much the same effects on the body as parathyroid extract. It raises the calcium level in blood and excreta and it also increases the absorption of calcium from the intestinal tract, the latter is not influenced by parathyroid extract. Vitamin D also has the advantage of maintaining these effects indefinitely, and it can be

given by mouth. Therefore it is often preferable to substitute vitamin D for parathyroid extract, particularly when prolonged administration is needed.

Vitamin D has a disadvantage as well. Whereas parathyroid extract takes a few hours to establish its effect, vitamin D takes days, and this is a serious consideration in an emergency. The effects of an overdosage of vitamin D last a long time and a hypercalcemia so induced lasts for two weeks or longer, so that the accompanying nausea, lack of appetite and other more serious signs are protracted. An overdosage of vitamin D, therefore, is highly undesirable.

USES OF PARATHYROID EXTRACT

Because its most outspoken effect is to raise the blood calcium level, the clinical use of parathyroid extract is most dramatically seen in patients with a low blood calcium tetany.
